

CS 423

Operating System Design: The Kernel Abstraction

Tianyin Xu

* Thanks for Prof. Adam Bates for the slides.

- MP 0 due is postponed to next Tue.
- C4 Paper Summary submitted to cs423sp20@gmail.com

Let's do something fun.

Let's start with some questions.

Process concept

- A process is the OS abstraction for executing a program with limited privileges

Dual-mode operation: user vs. kernel

- Kernel-mode: execute with complete privileges
- User-mode: execute with fewer privileges

Safe control transfer

- How do we switch from one mode to the other?

Process Abstraction

Process: an instance of a program that runs with limited rights on the machine

- Thread: a sequence of instructions within a process
 - Potentially many threads per process (for now, assume 1:1)
- Address space: set of rights of a process
 - Memory that the process can access
 - Other permissions the process has (e.g., which system calls it can make, what files it can access)

How can we permit a process to execute with only limited privileges?

Thought Experiment

How can we implement execution with limited privilege?

- Execute each program instruction in a simulator
- If the instruction is permitted, do the instruction
- Otherwise, stop the process
- Basic model in Javascript and other interpreted languages

Thought Experiment

How can we implement execution with limited privilege?

- Execute each program instruction in a simulator
- If the instruction is permitted, do the instruction
- Otherwise, stop the process
- Basic model in Javascript and other interpreted languages

Ok... but how do we go faster?

Thought Experiment

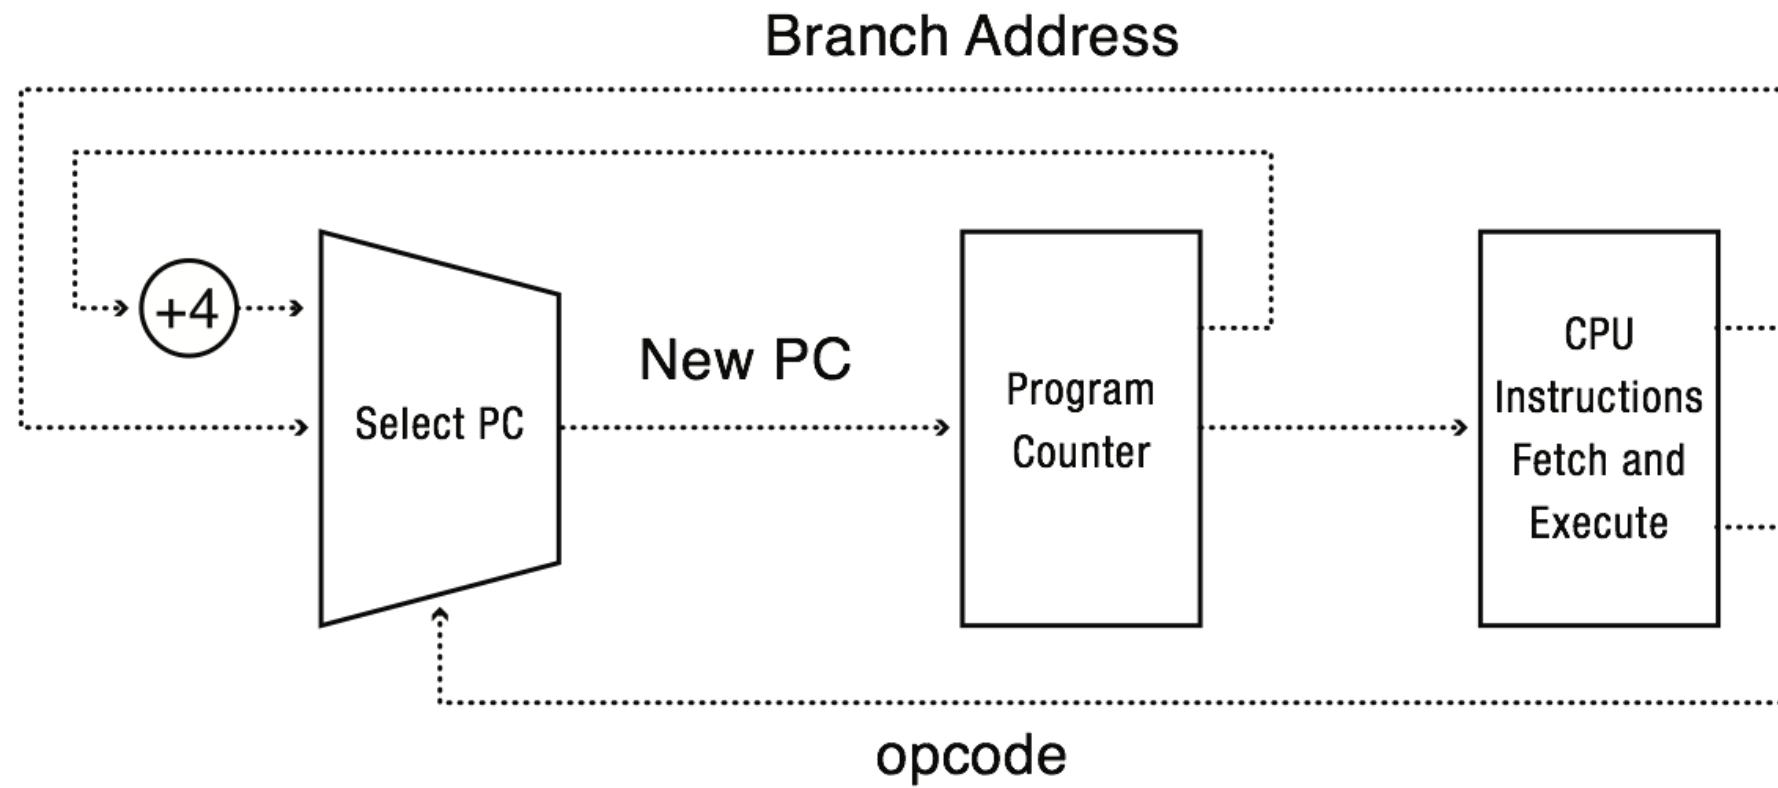

How can we implement execution with limited privilege?

- Execute each program instruction in a simulator
- If the instruction is permitted, do the instruction
- Otherwise, stop the process
- Basic model in Javascript and other interpreted languages

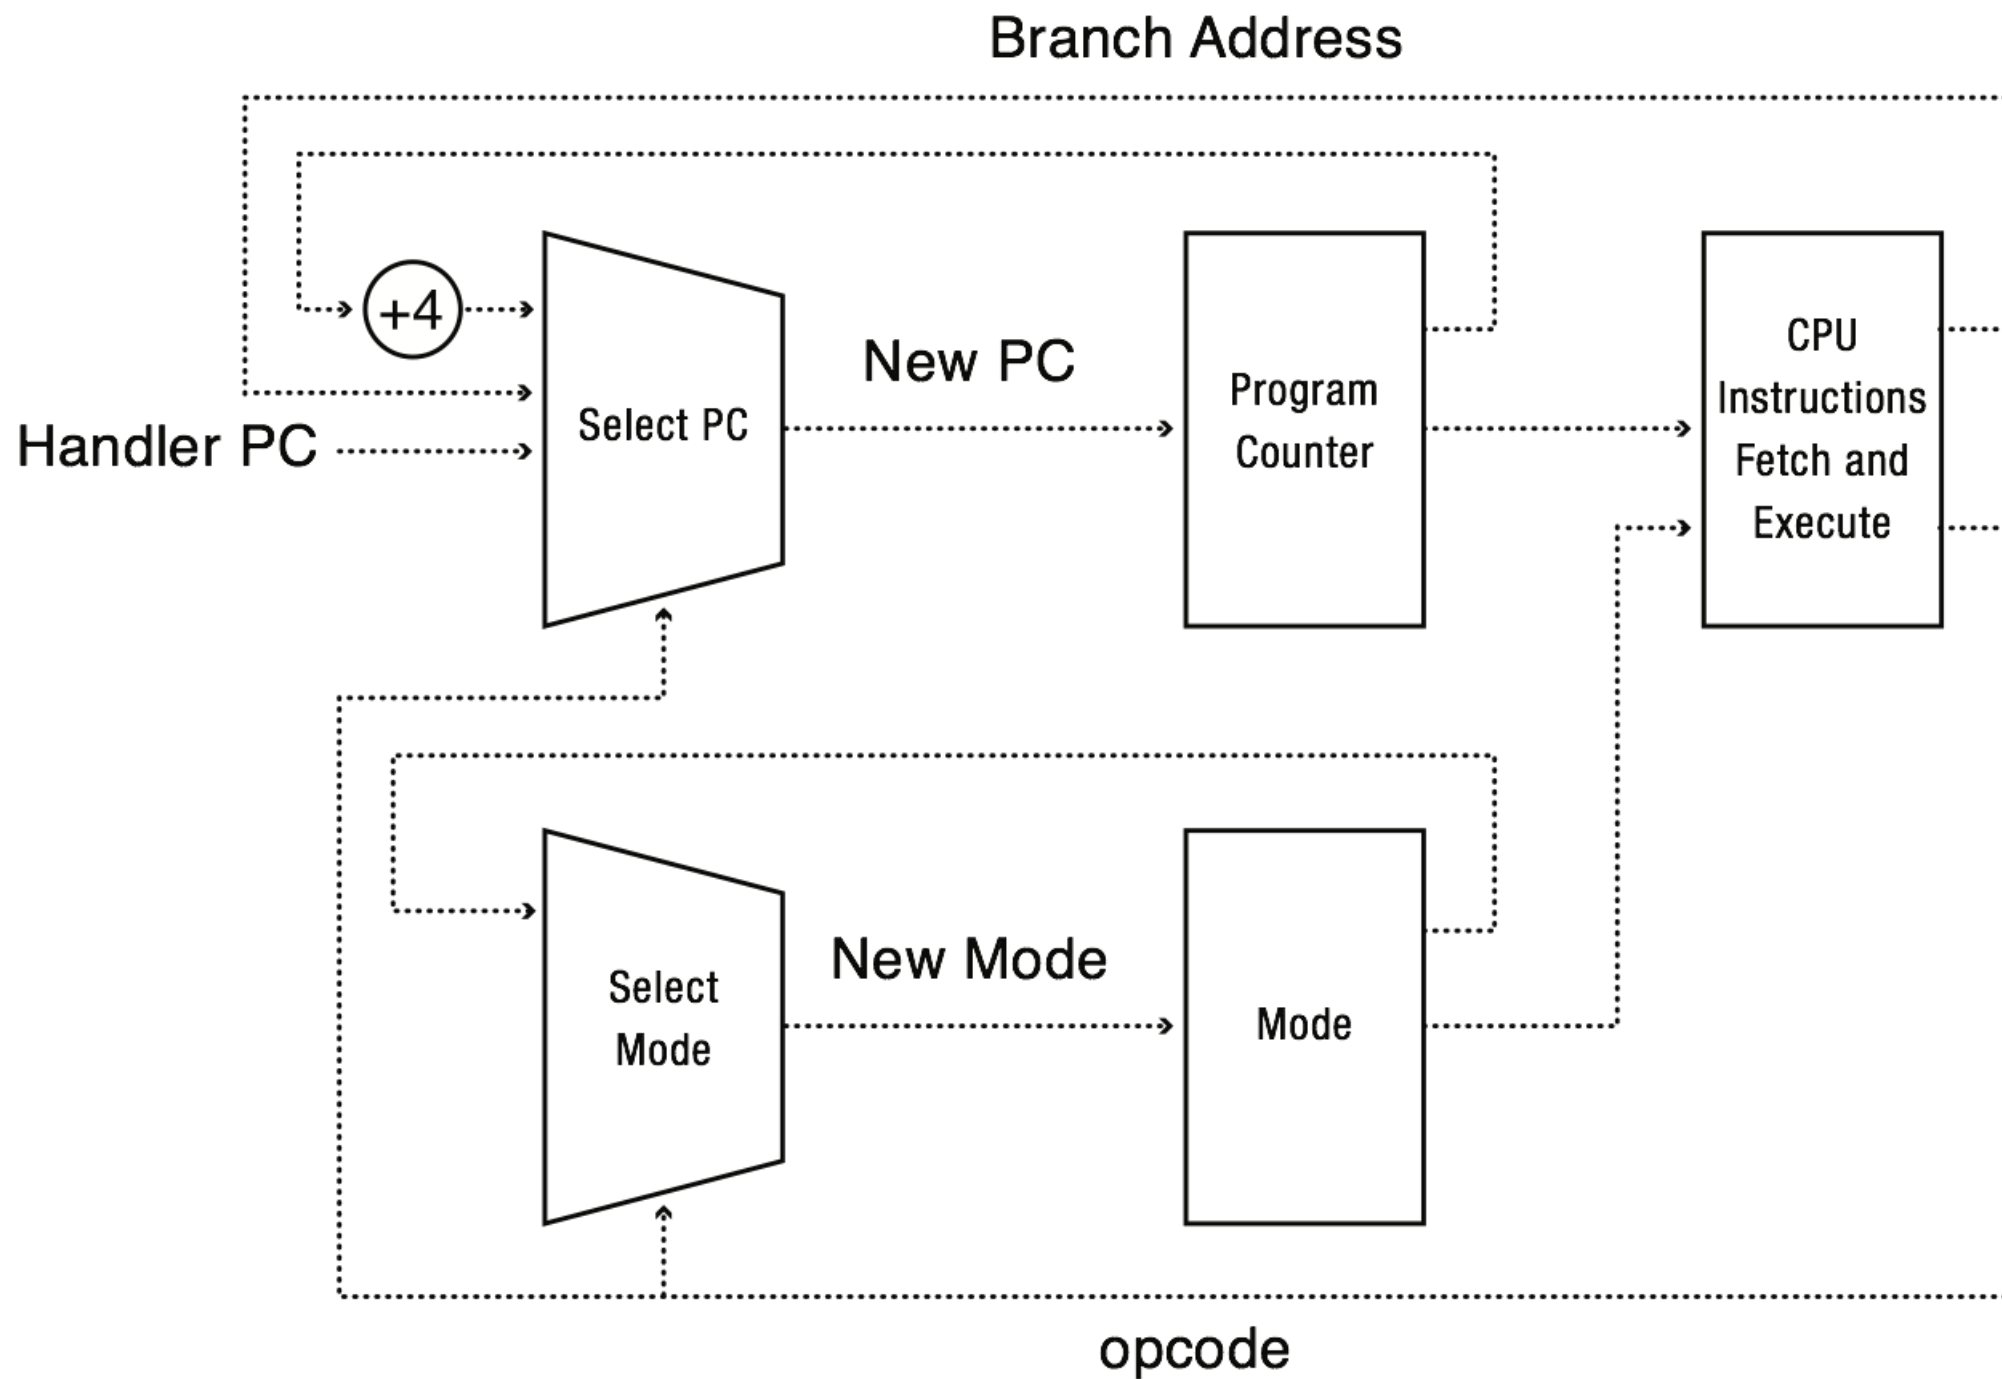

Ok... but how do we go faster?

- Run the unprivileged code directly on the CPU!

A Model of a CPU

A CPU with Dual-Mode Operation

Privileged instructions

- Available to kernel
- Not available to user code

Limits on memory accesses

- To prevent user code from overwriting the kernel

Timer

- To regain control from a user program in a loop

Safe way to switch from user mode to kernel mode,
and vice versa

Privileged Instructions

Examples?

What should happen if a user program attempts to execute a privileged instruction?

User->Kernel Switches

How/when do we switch from user to kernel mode?

1. Interrupts
 - Triggered by timer and I/O devices
2. Exceptions
 - Triggered by unexpected program behavior
 - Or malicious behavior!
3. System calls (aka protected procedure call)
 - Request by program for kernel to do some operation on its behalf
 - Only limited # of very carefully coded entry points

**How does the OS know
when a process is in an
infinite loop?**

Hardware Timer

Hardware device that periodically interrupts the processor

- Returns control to the kernel handler
- Interrupt frequency set by the kernel
Not by user code!
- Interrupts can be temporarily deferred
Not by user code! Interrupt deferral crucial for implementing mutual exclusion

Kernel->User Switches

How/when do we switch from kernel to user mode?

1. New process/new thread start
 - Jump to first instruction in program/thread
2. Return from interrupt, exception, system call
 - Resume suspended execution (return to PC)
3. Process/thread context switch
 - Resume some other process (return to PC)
4. User-level upcall (UNIX signal)
 - Asynchronous notification to user program

CPU State

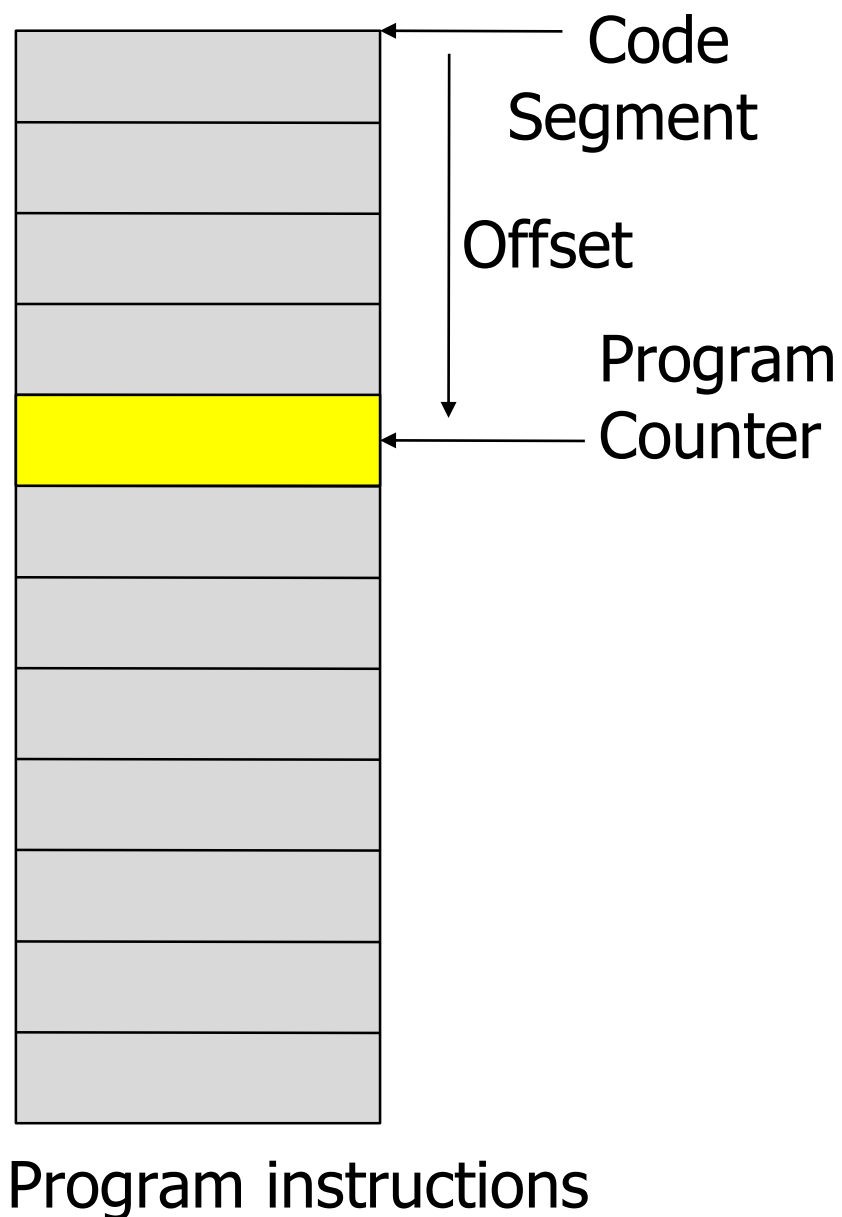

What is the CPU's behavior defined by at any given moment?

CPU State

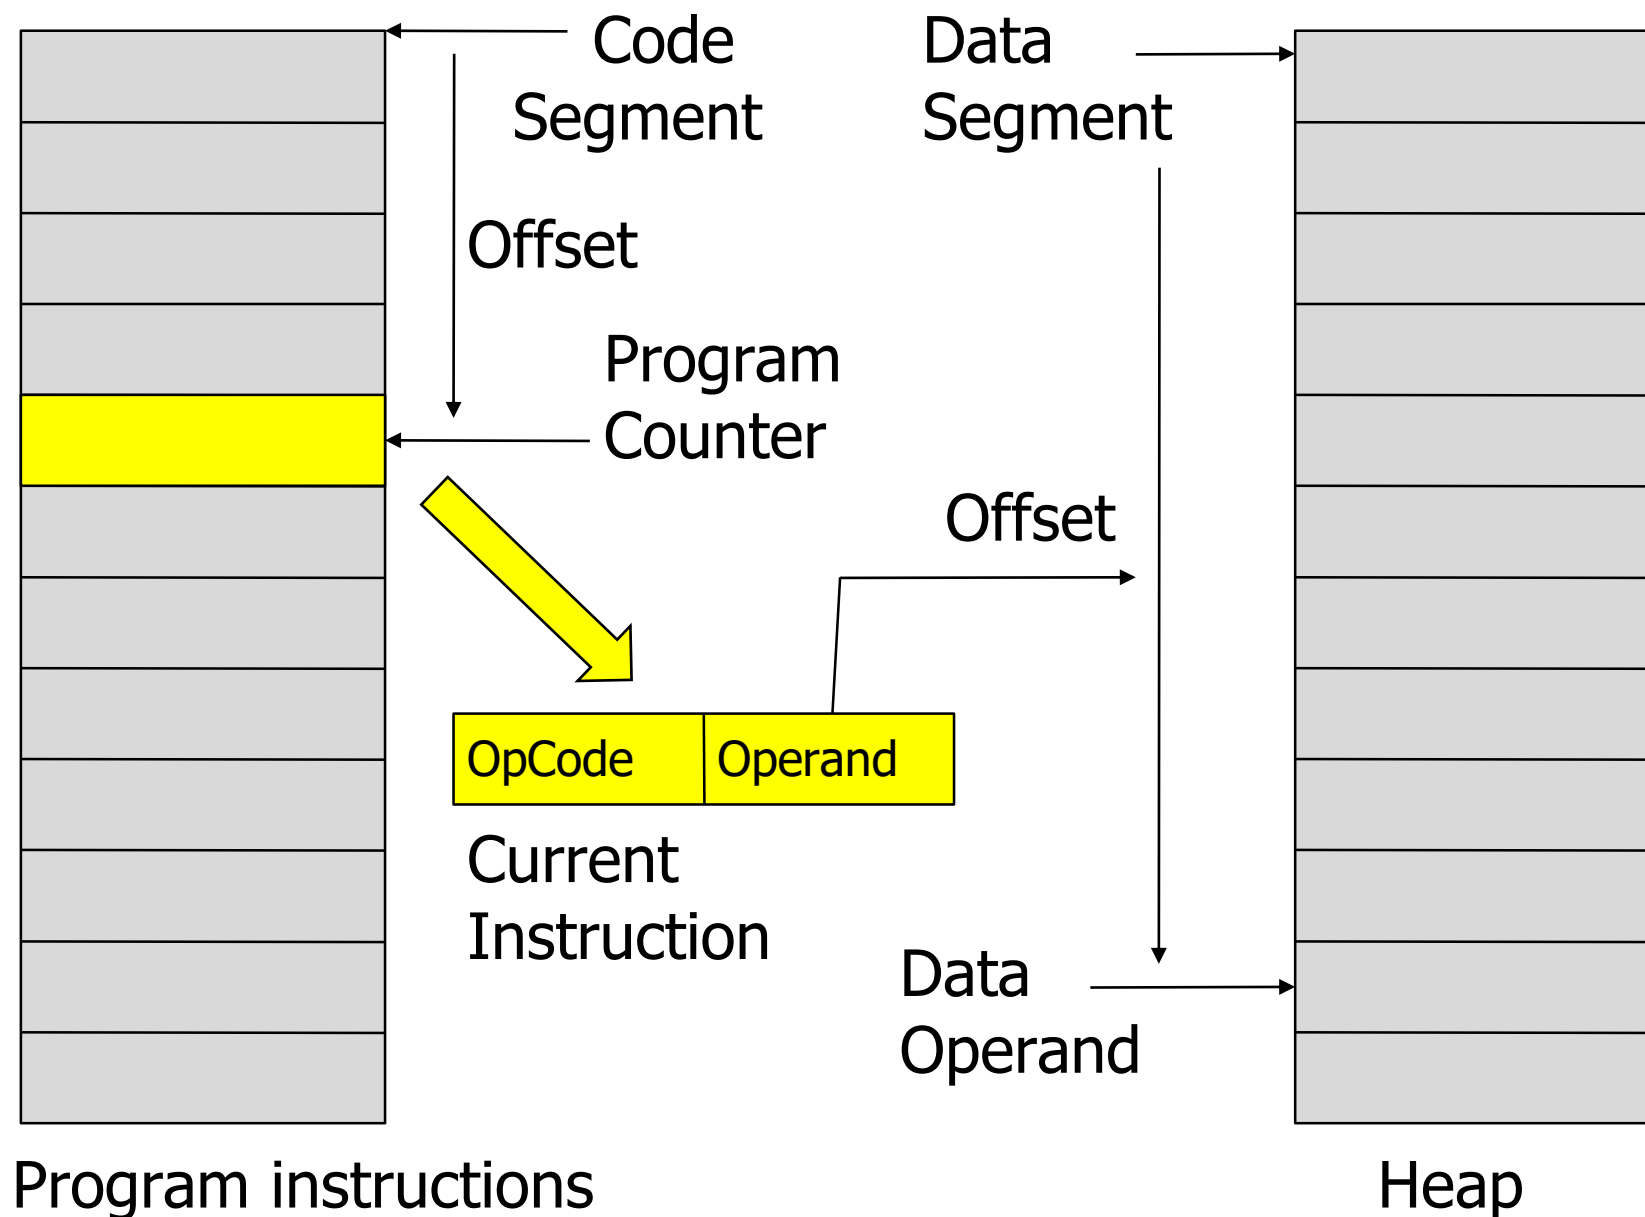

What is the CPU's behavior defined by at any given moment?

CPU State

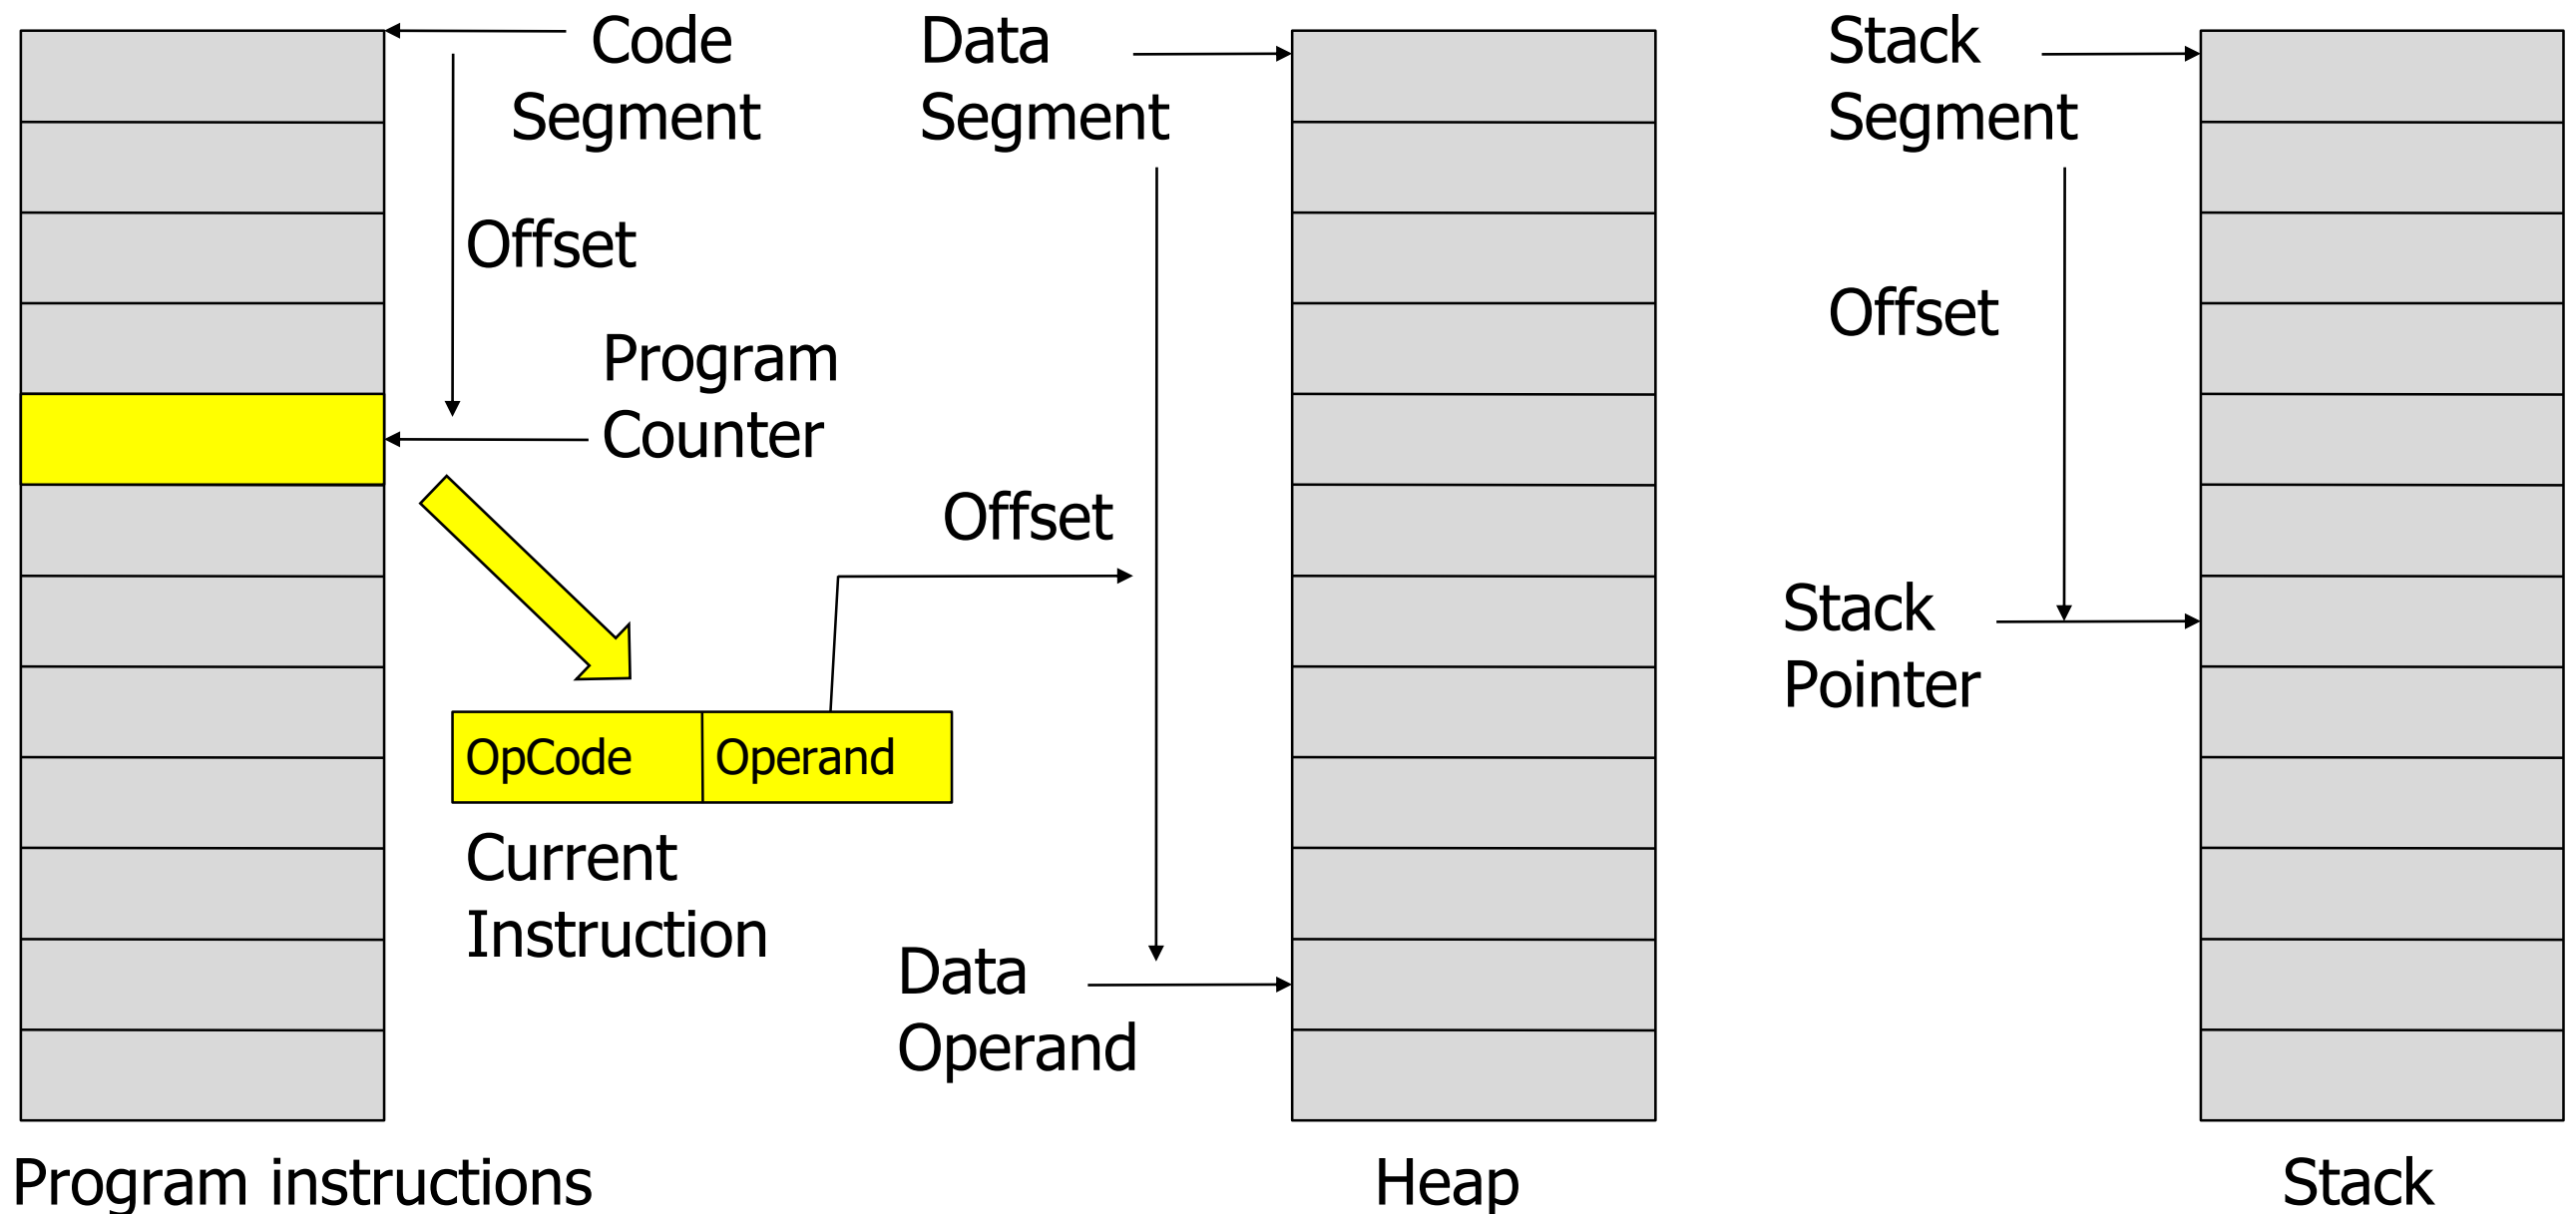

What is the CPU's behavior defined by at any given moment?

CPU State

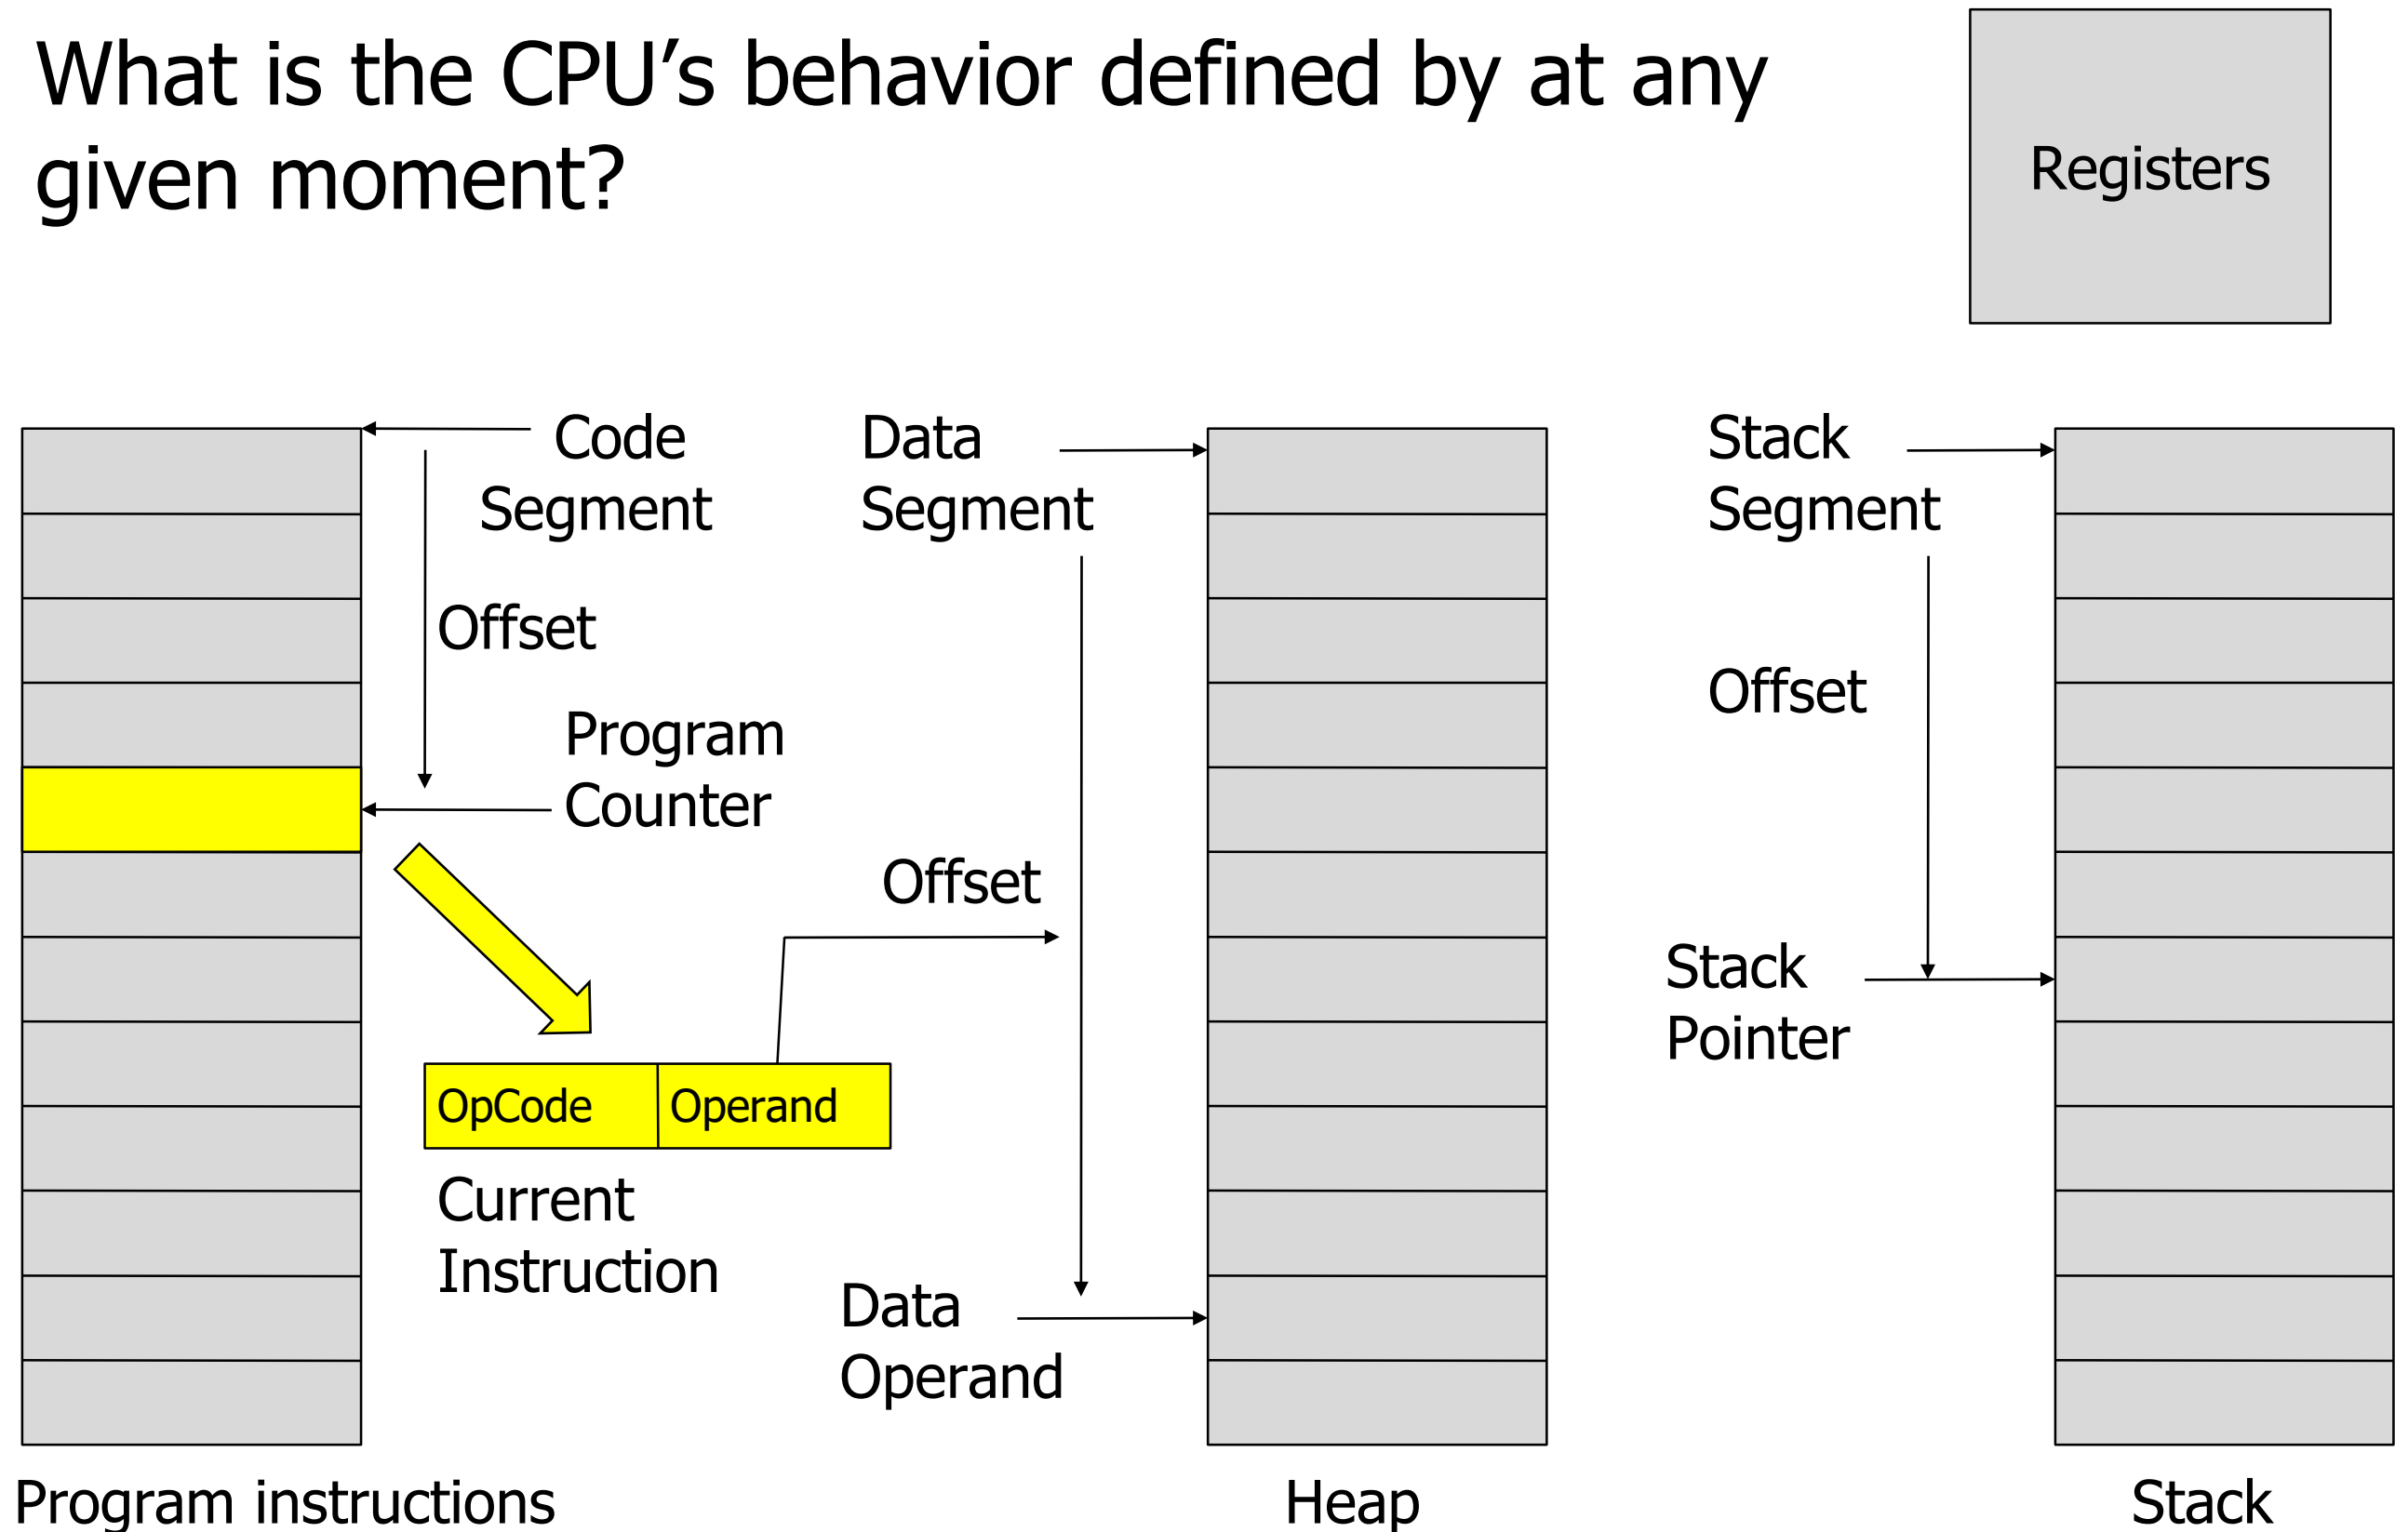

What is the CPU's behavior defined by at any given moment?

CPU State

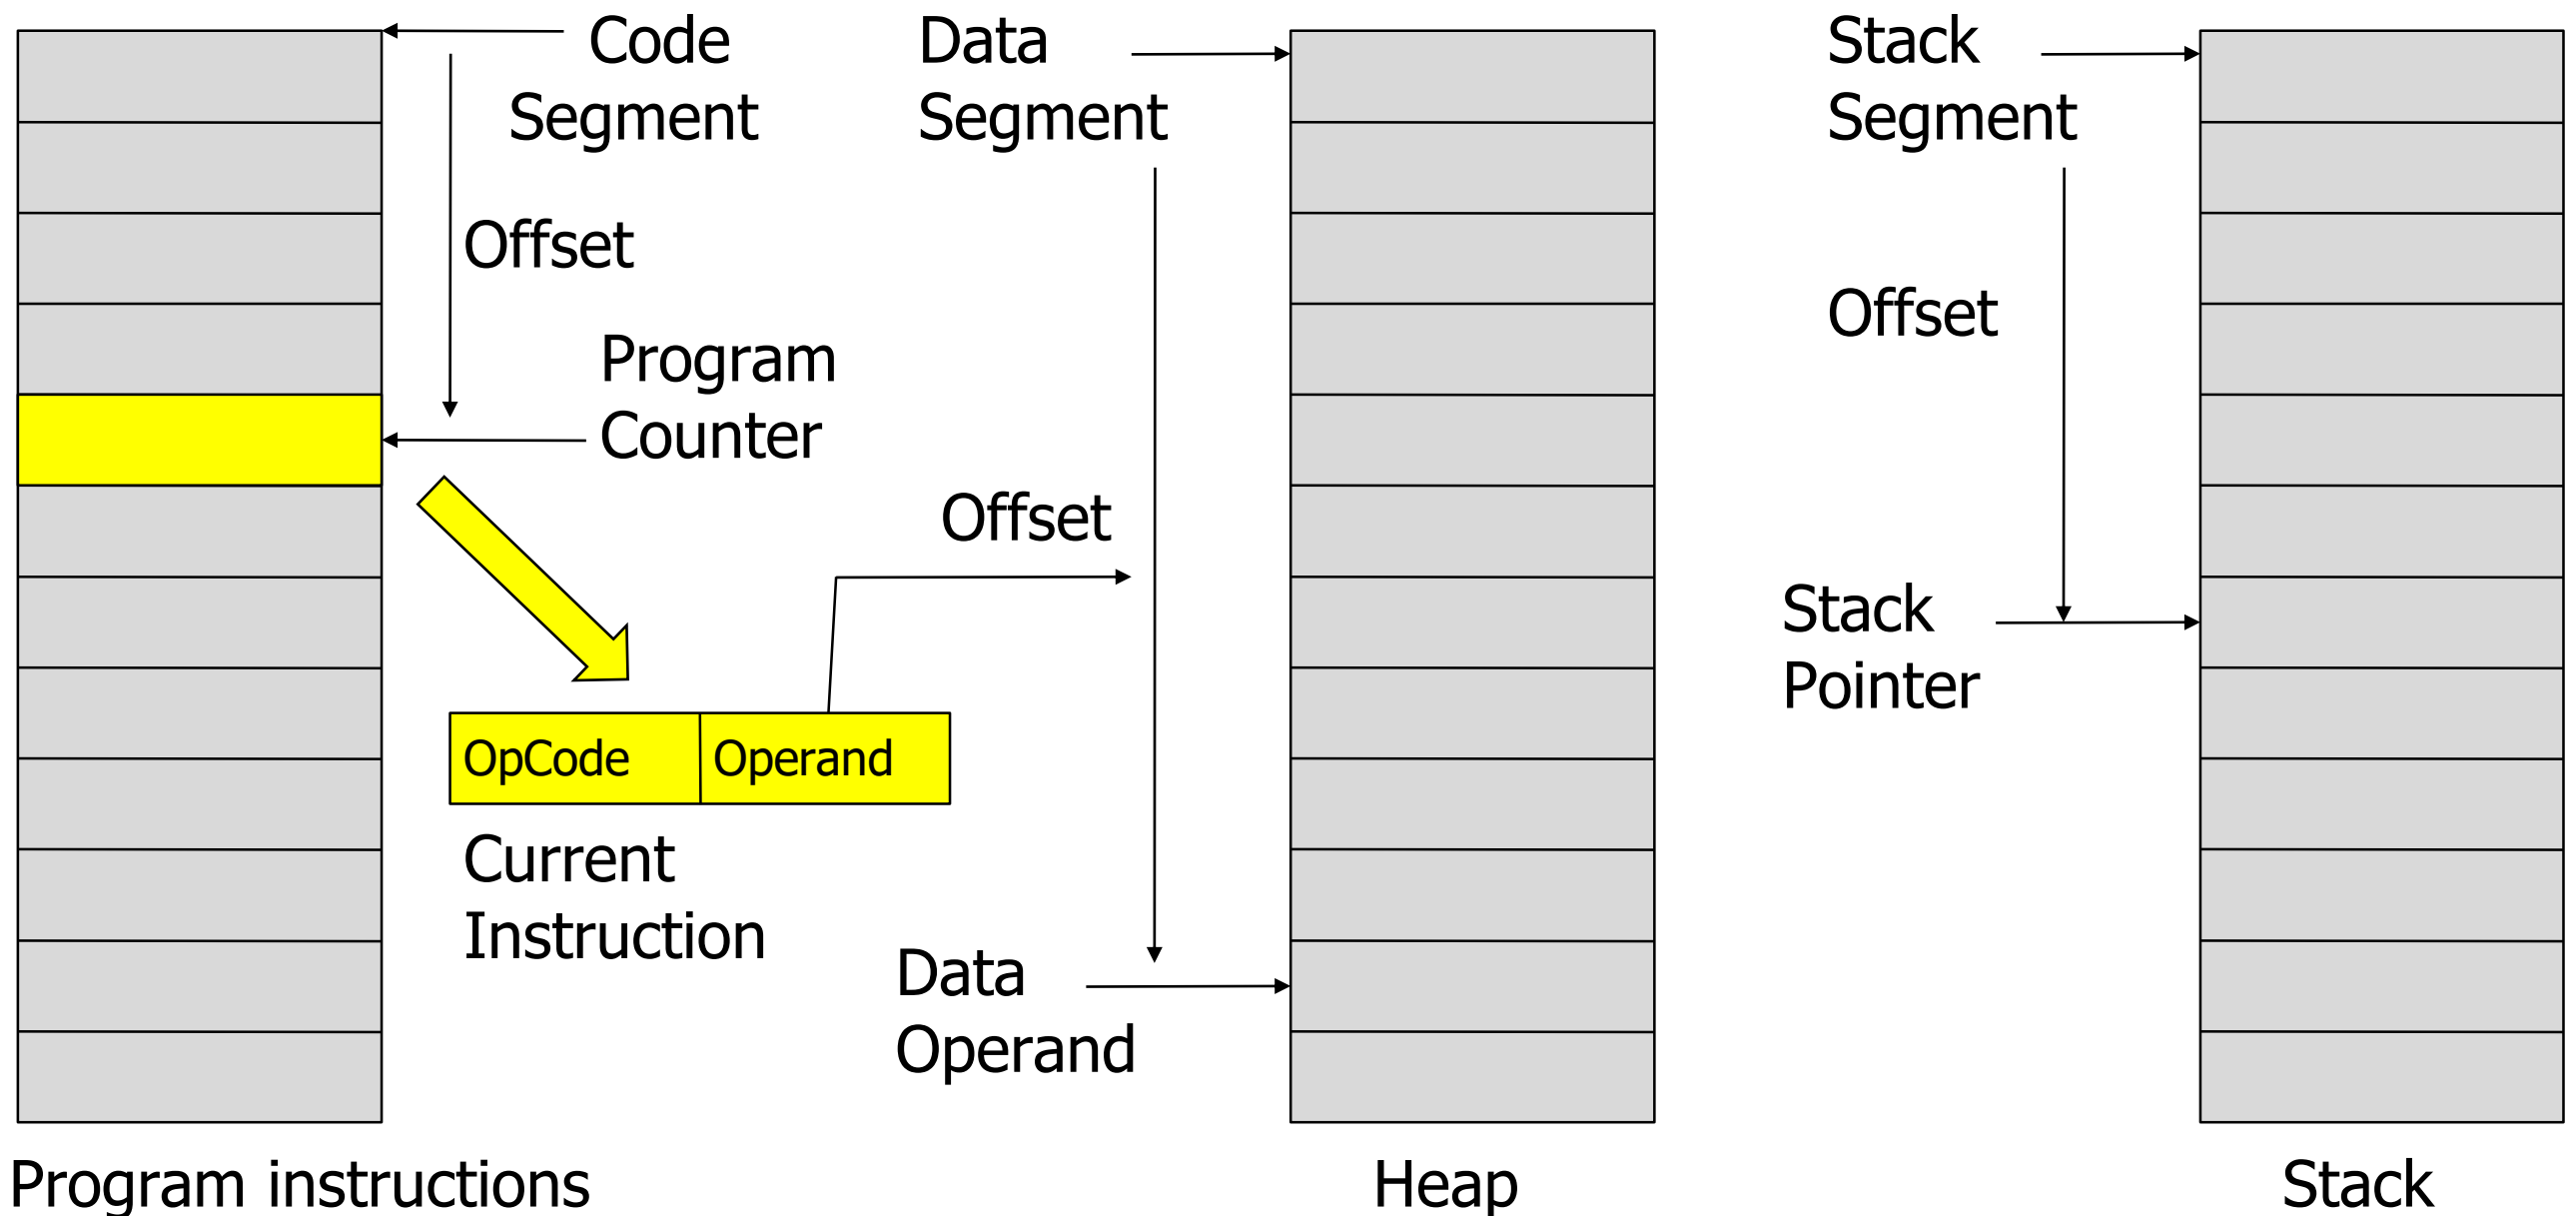

What is the CPU's behavior defined by at any given moment?

What defines the **STATE** of the CPU?

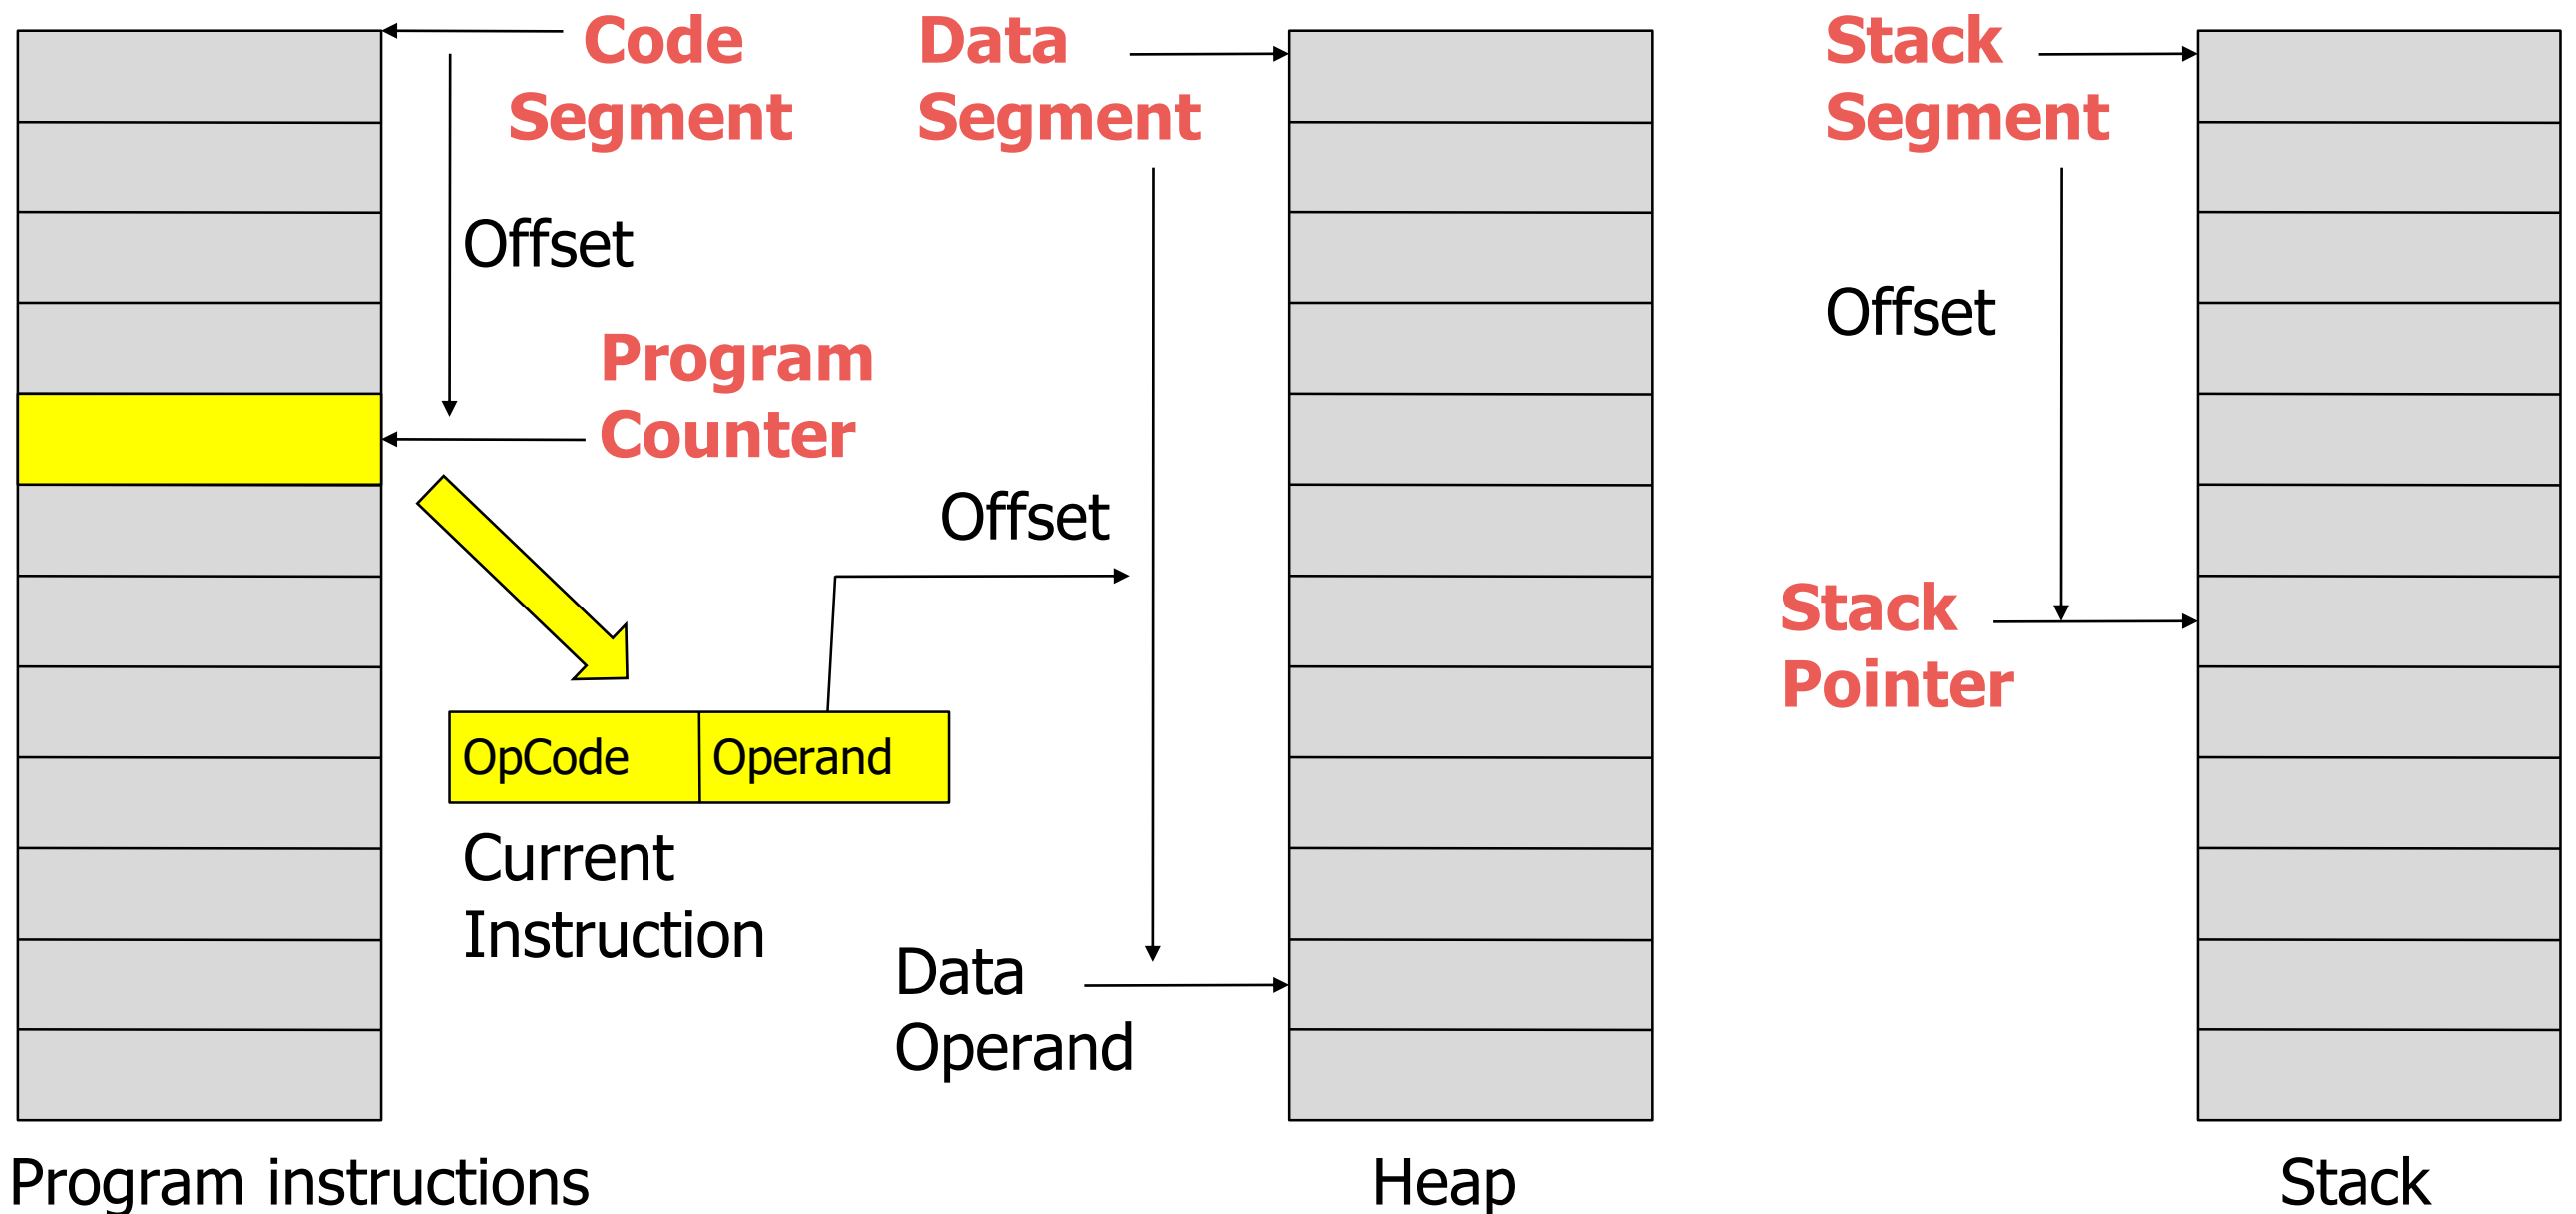

Registers

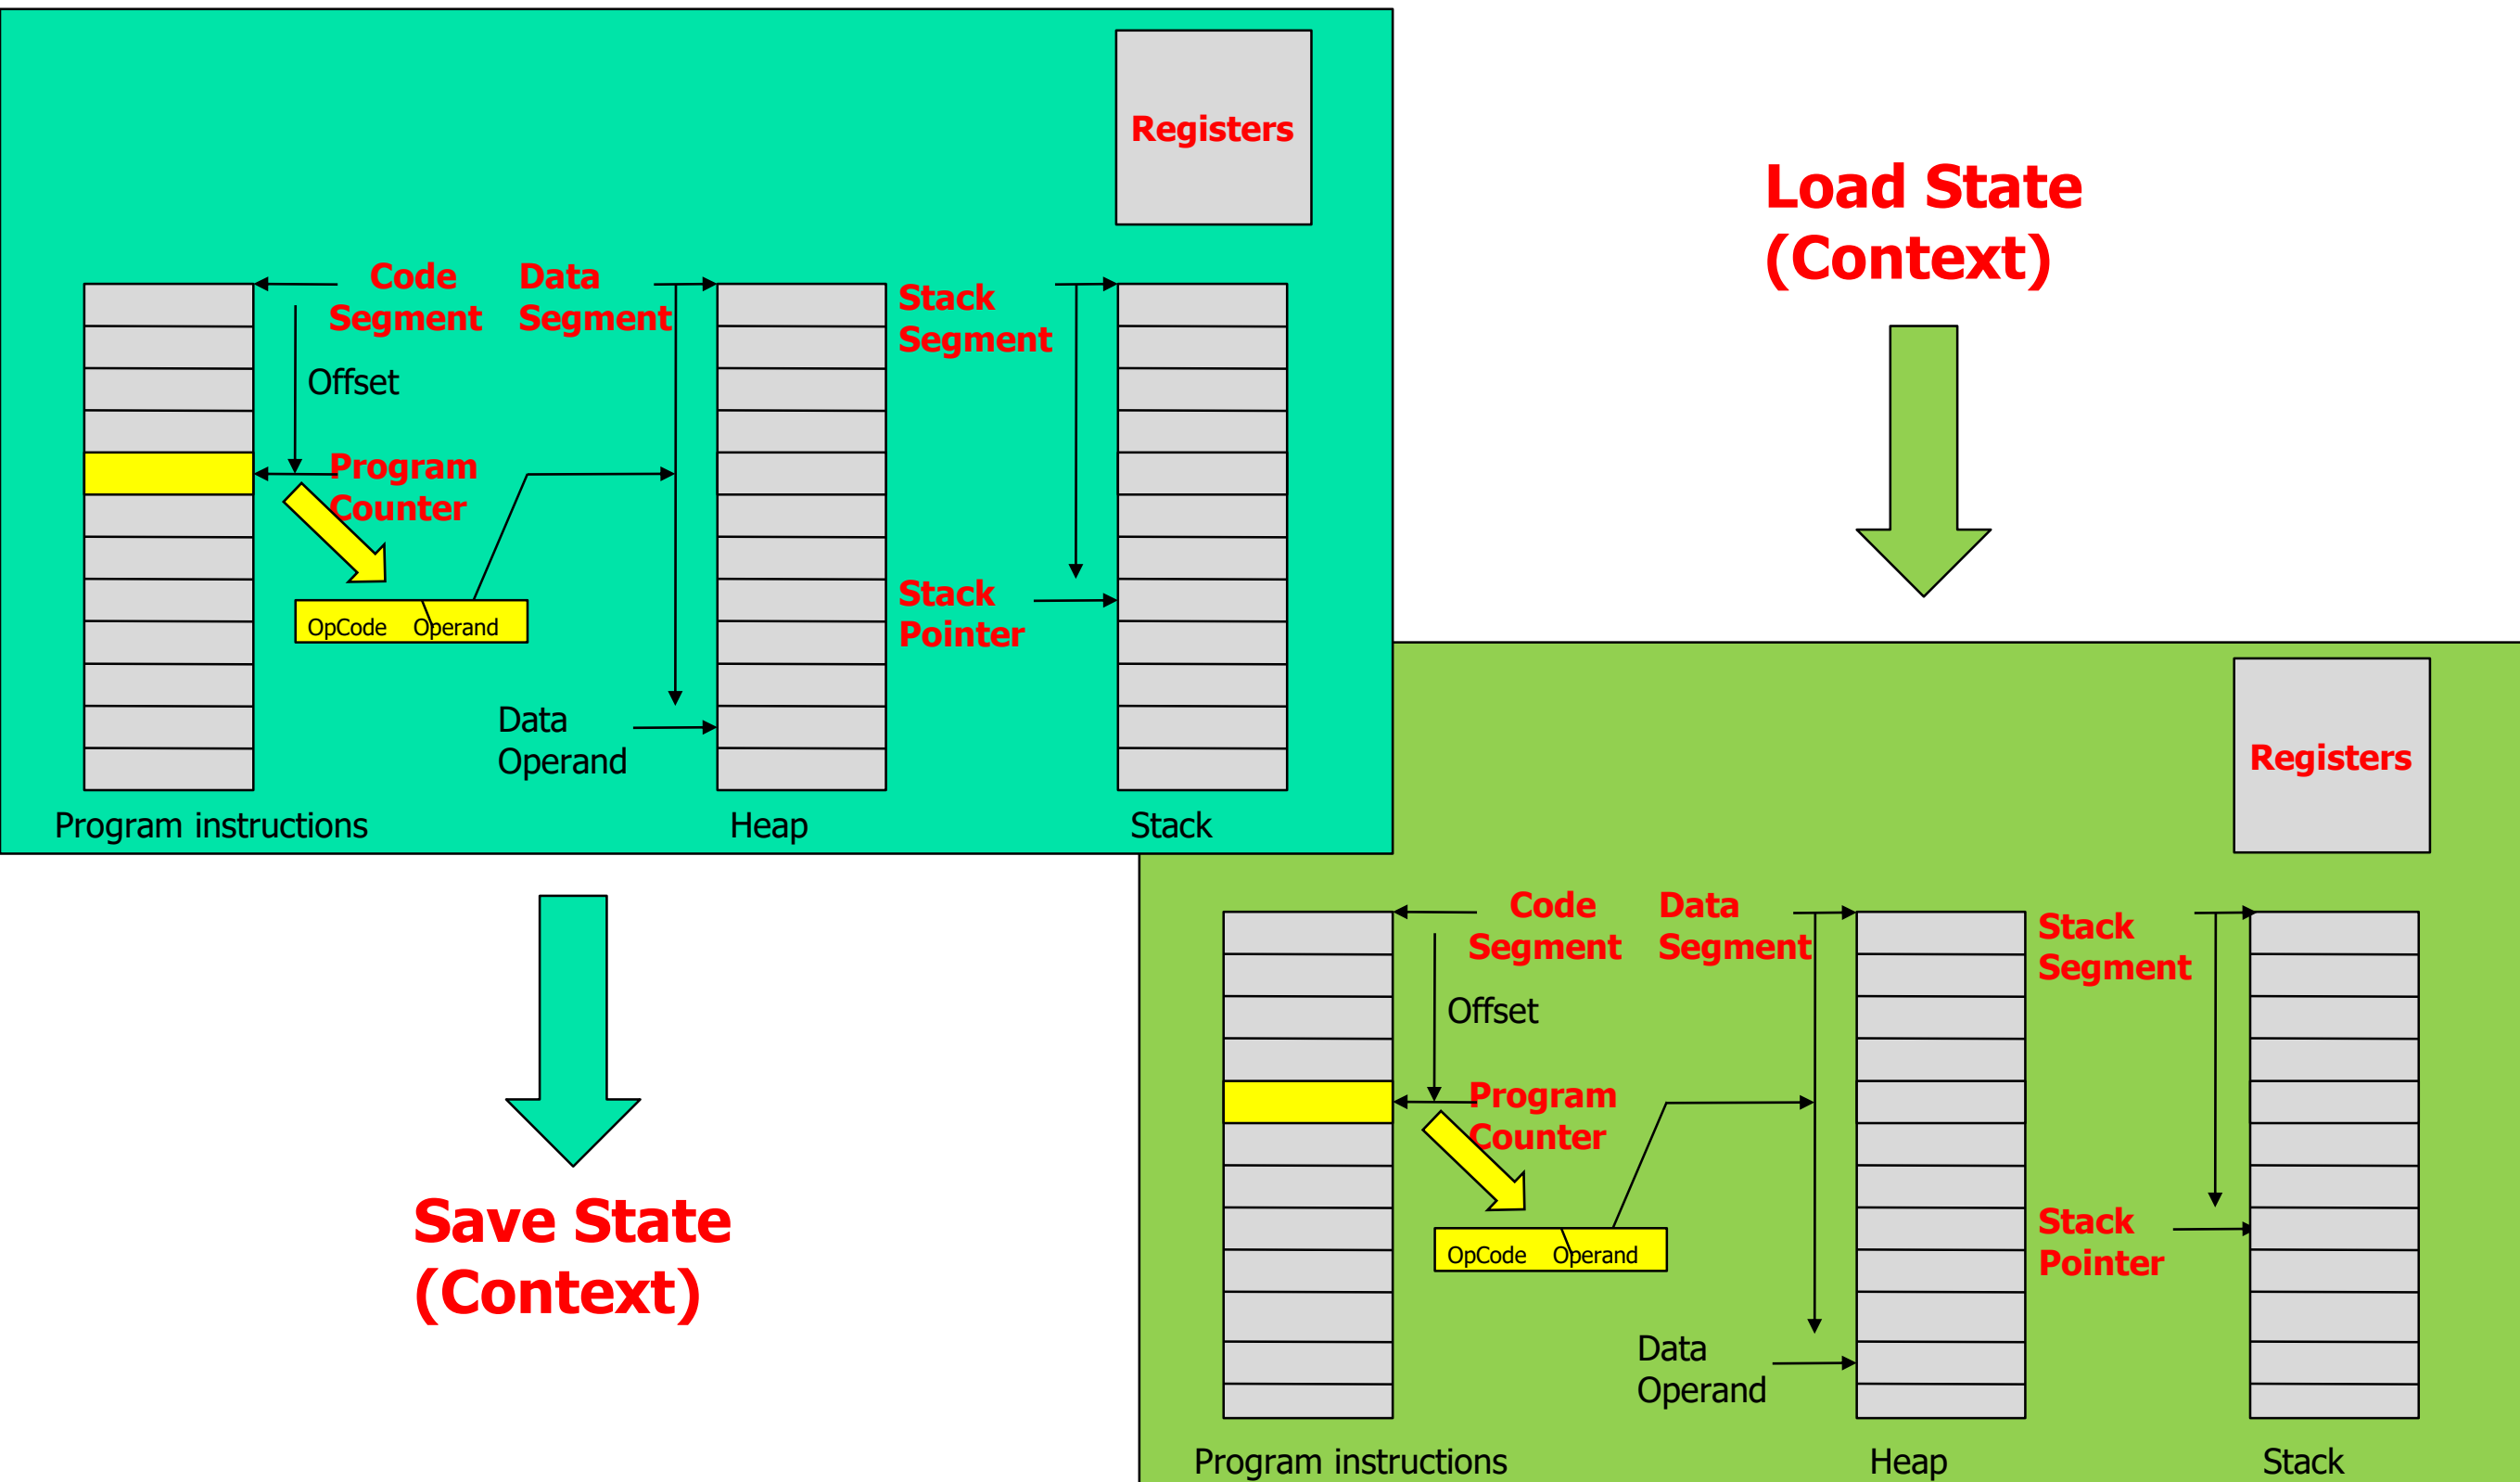

What's a 'real' CPU?

What's the **STATE** of a real CPU?

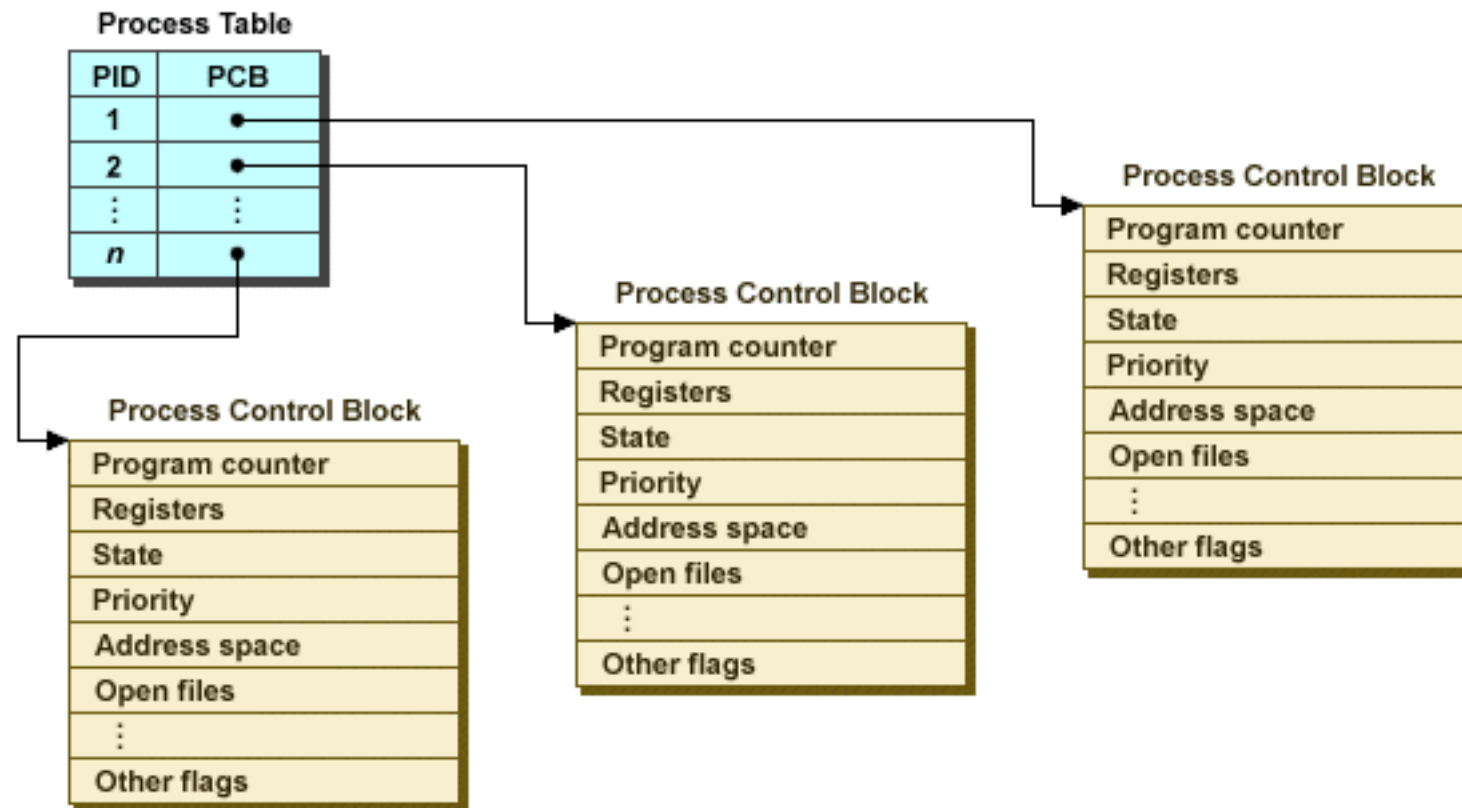

The Context Switch

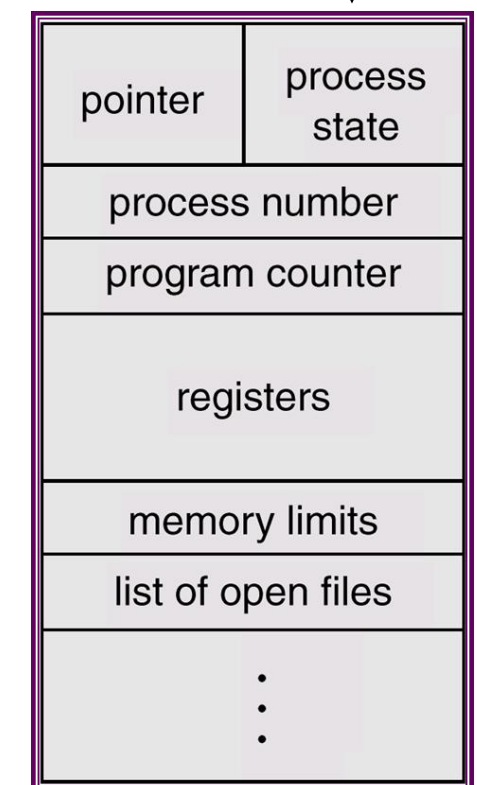

Process Control Block

The state for processes that are not running on the CPU are maintained in the Process Control Block (PCB) data structure

Updated during context switch

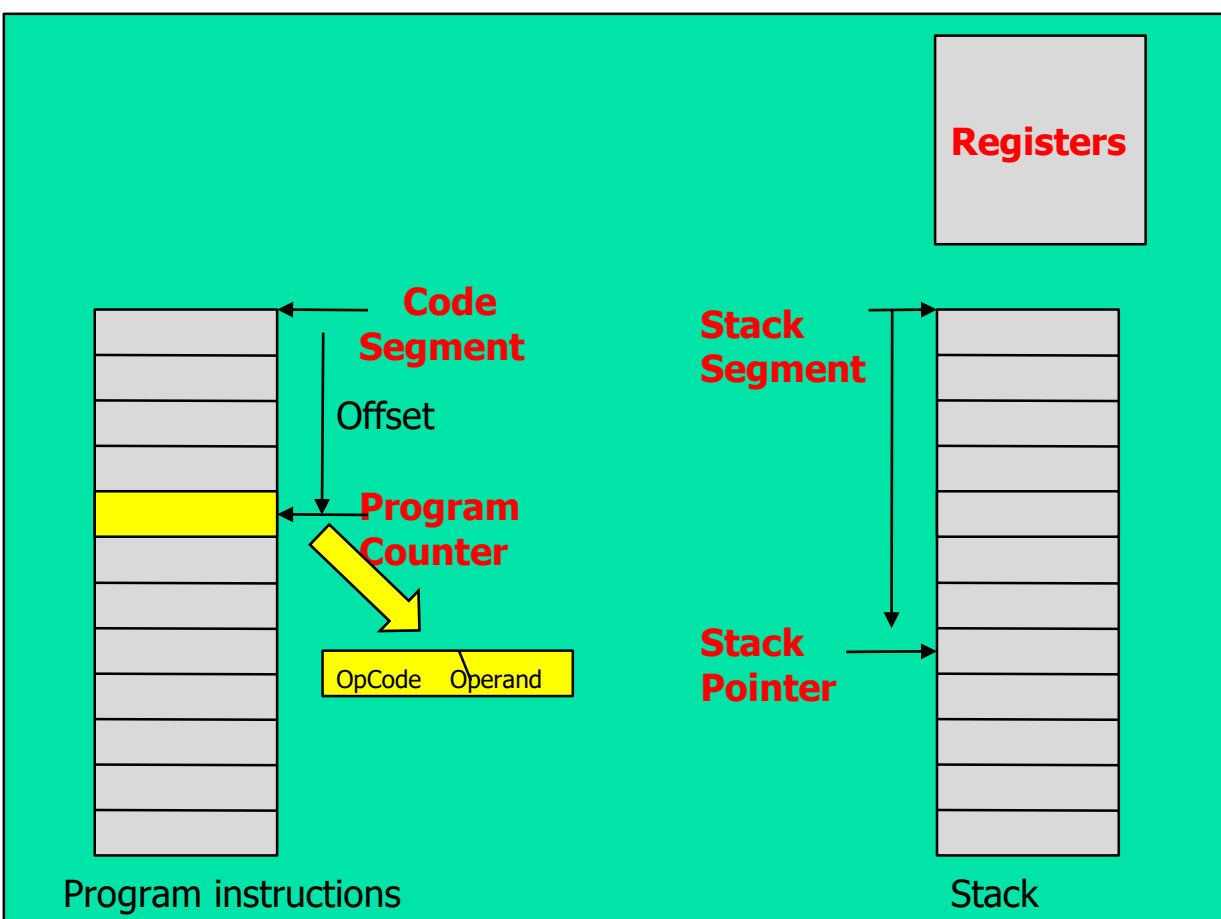

An alternate PCB diagram

The Context Switch

The Context Switch

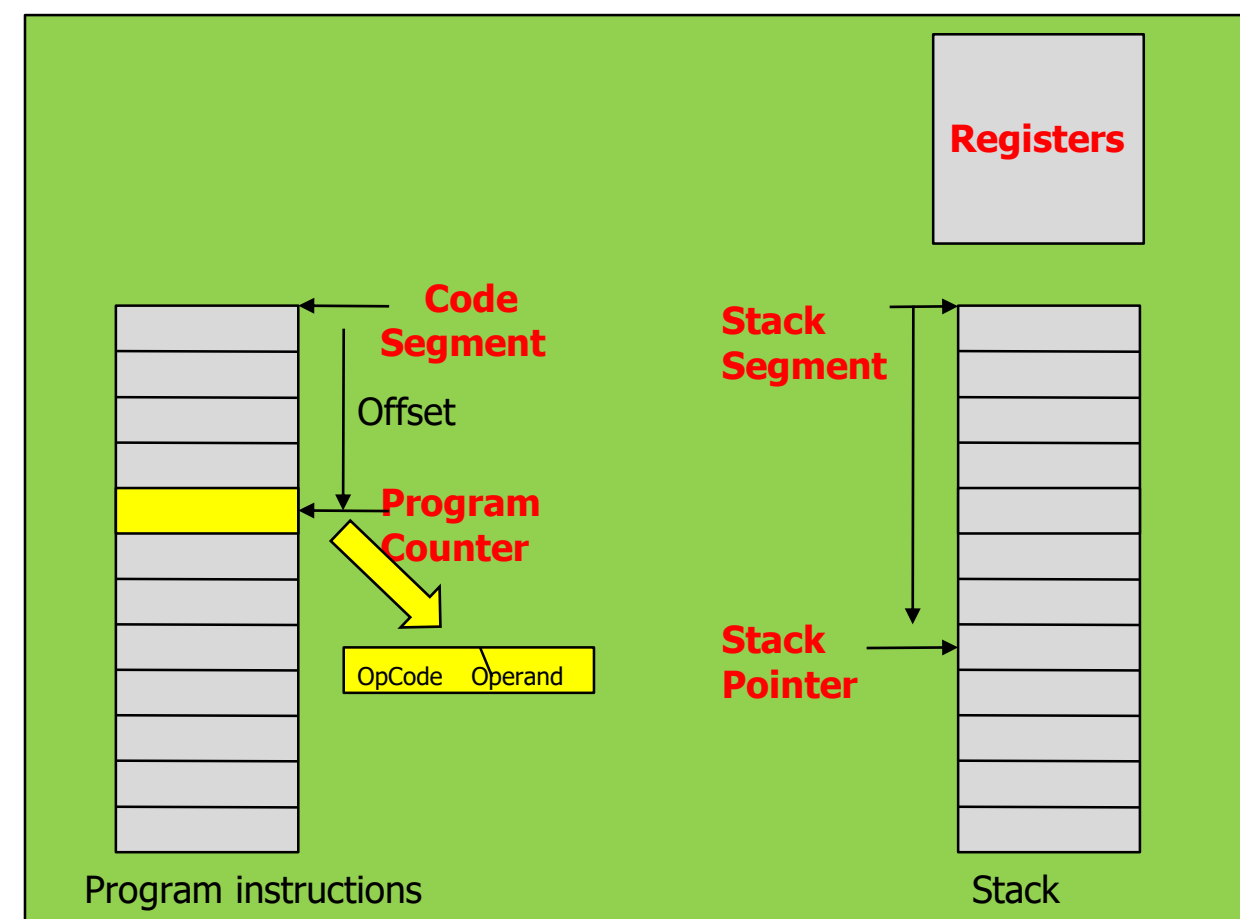

**Save State
(Context)**

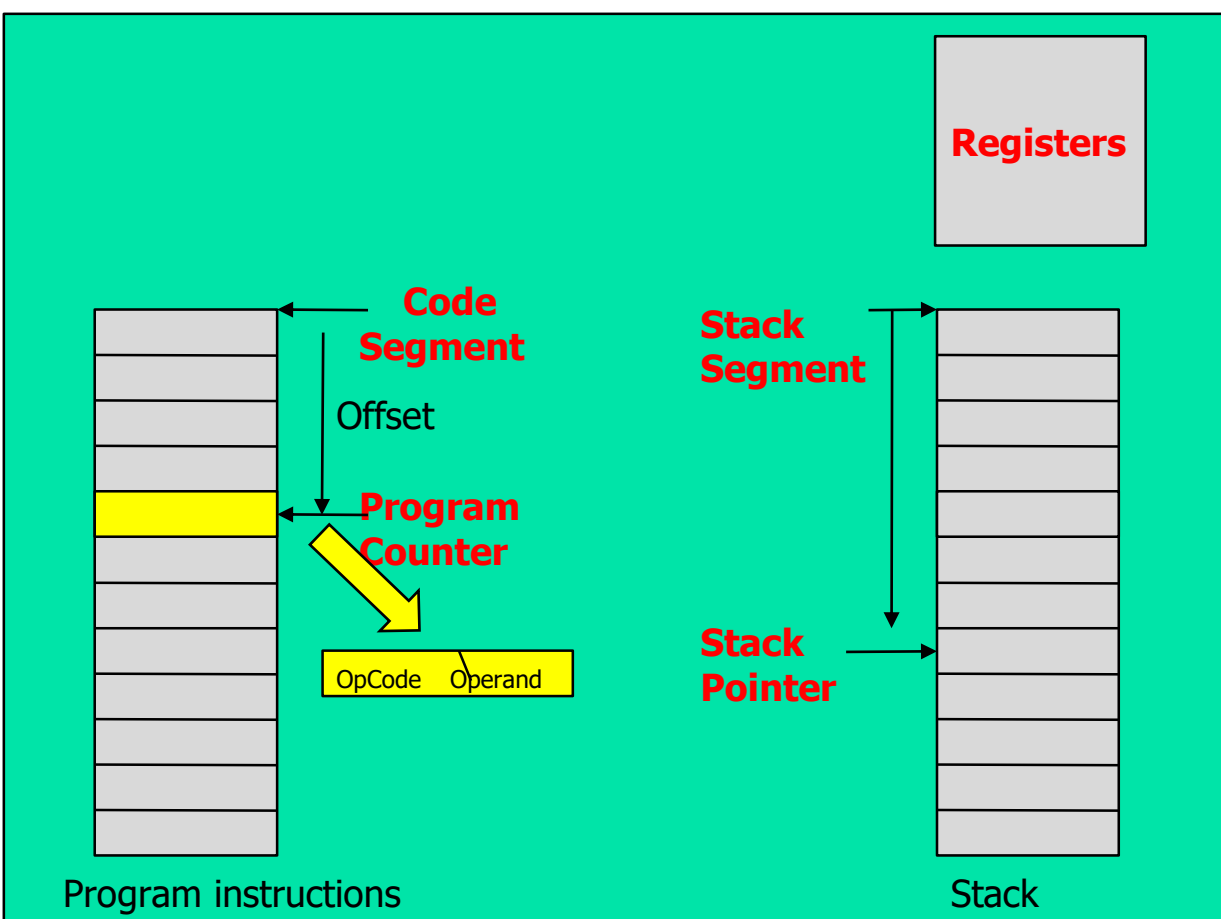

Note: In **thread** context switches, heap is not switched!

**Load State
(Context)**

Thread Context Switch

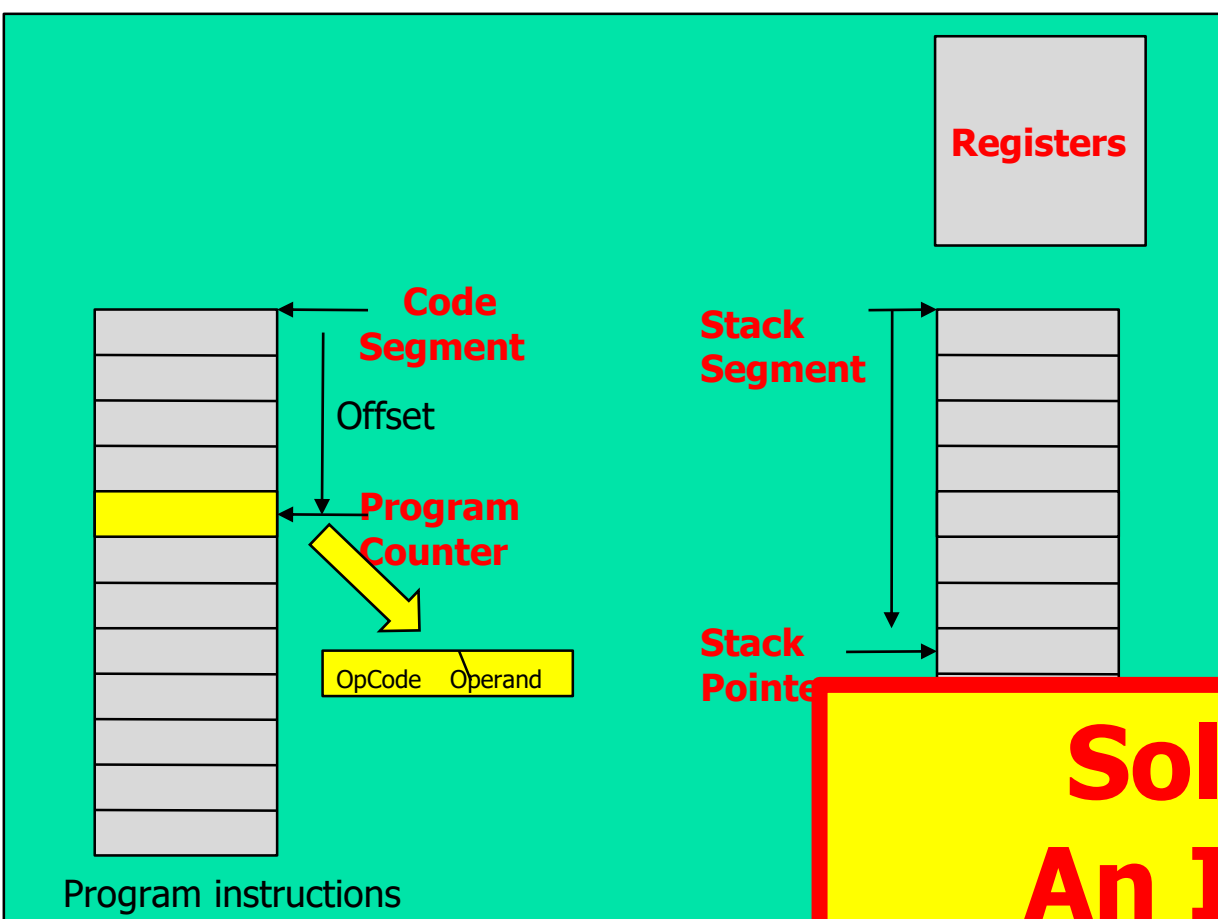

Note: In **thread** context switches, heap is not switched!

**Load State
(Context)**

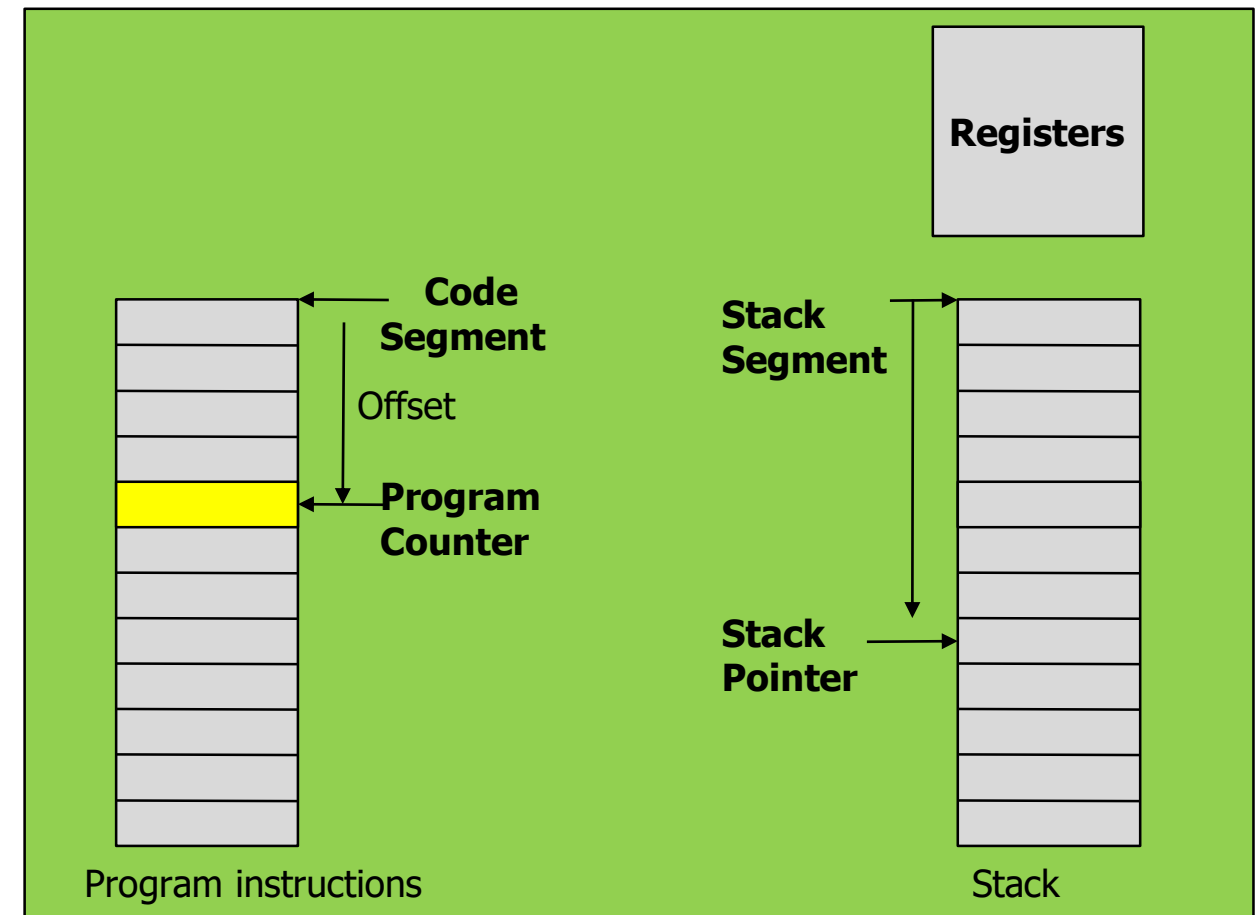

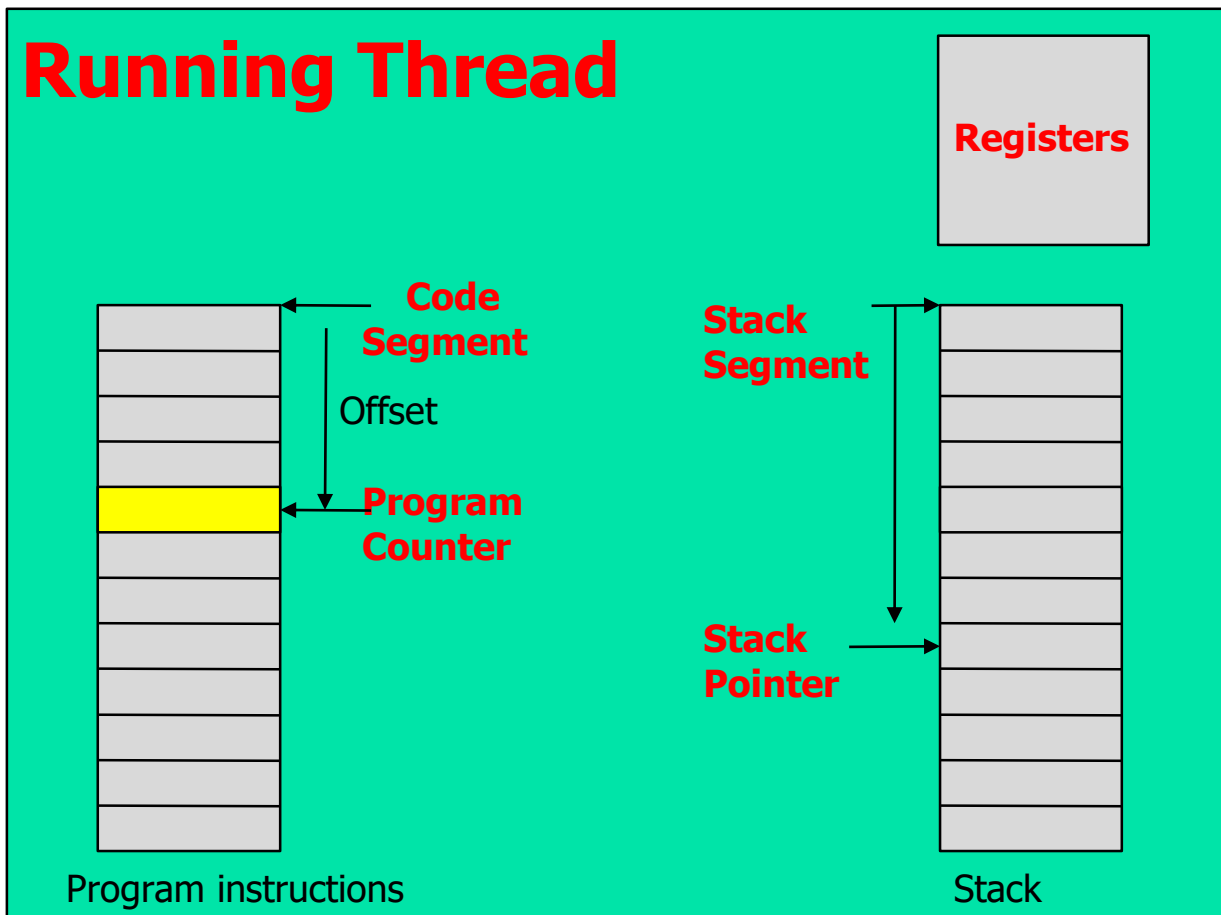

**Solution 1:
An Interrupt**

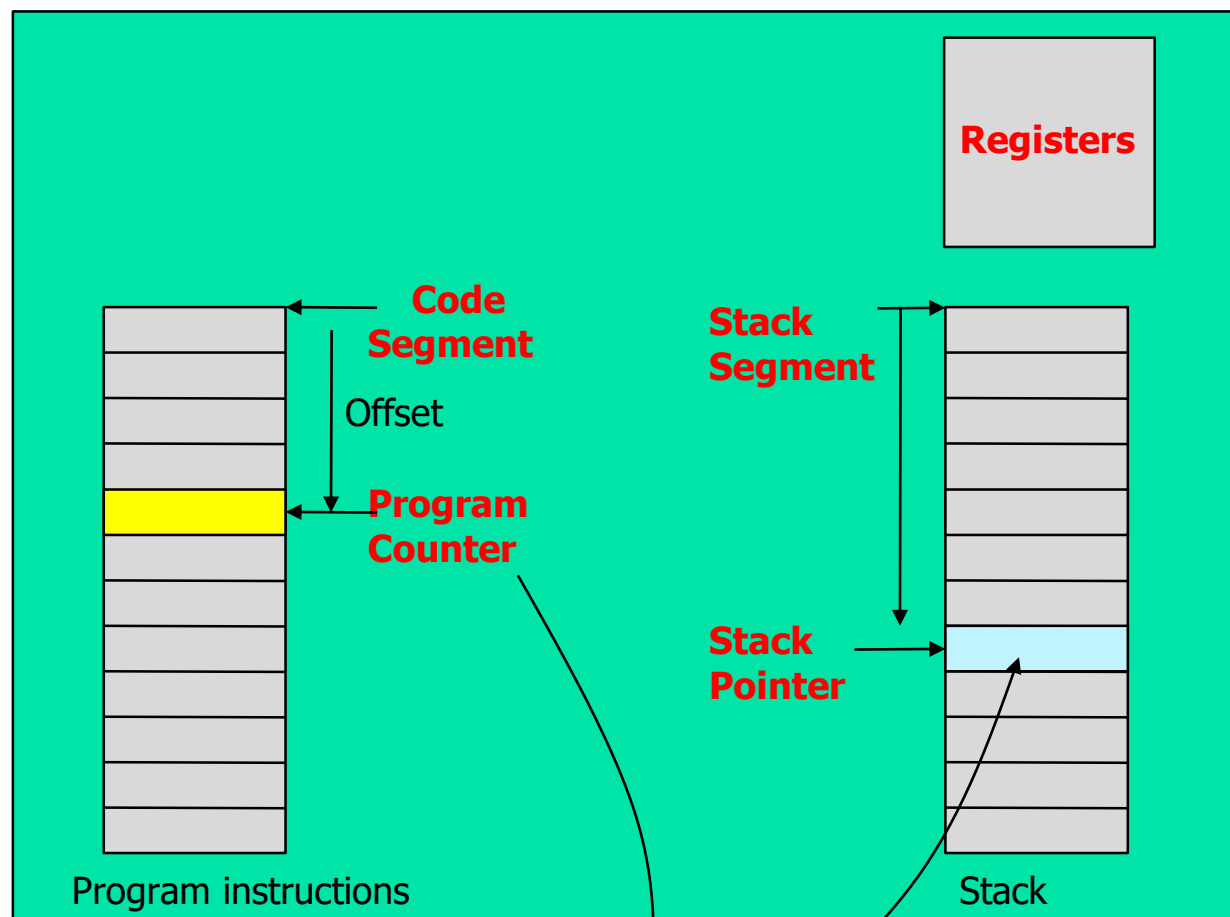

**Save State
(Context)**

CTX Switch: Interrupt

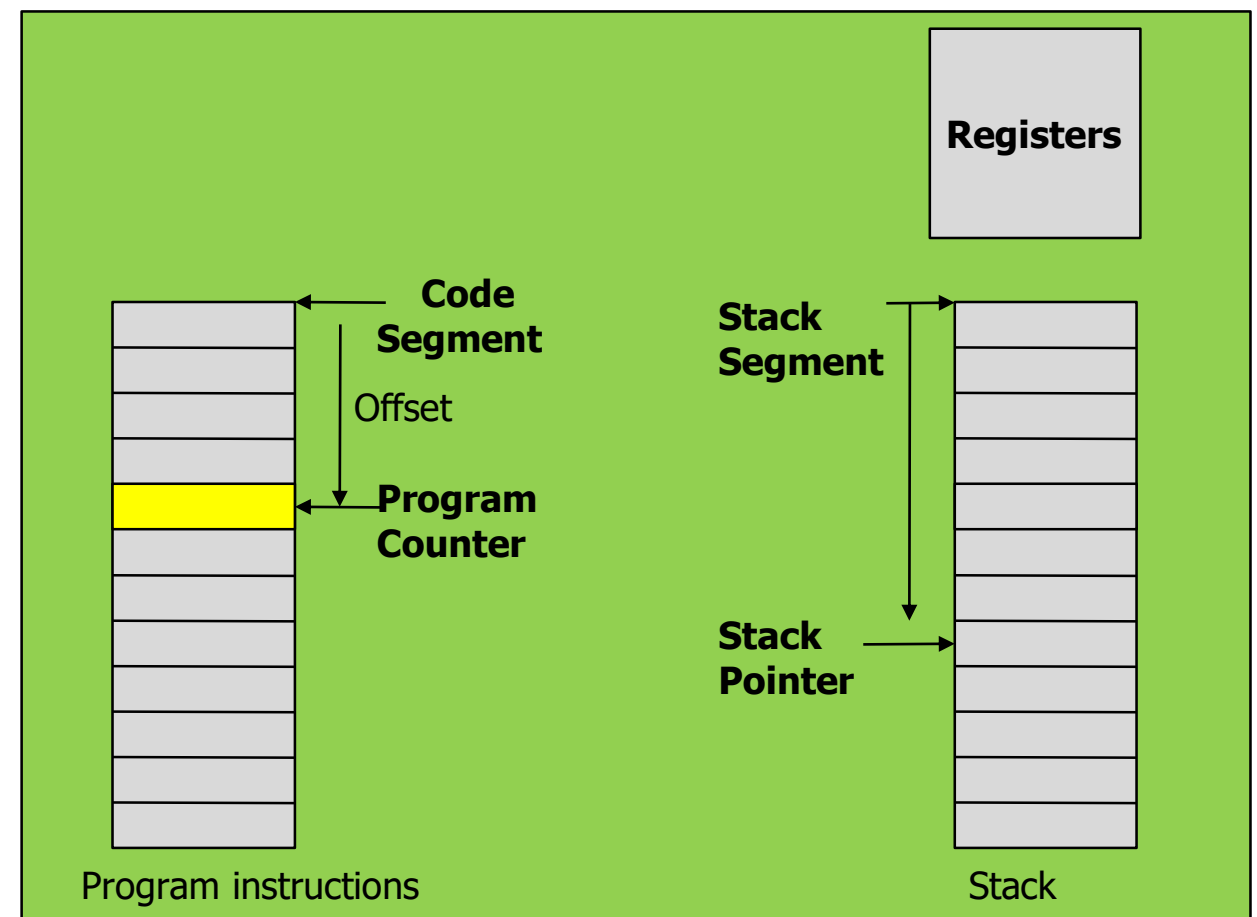

CTX Switch: Interrupt

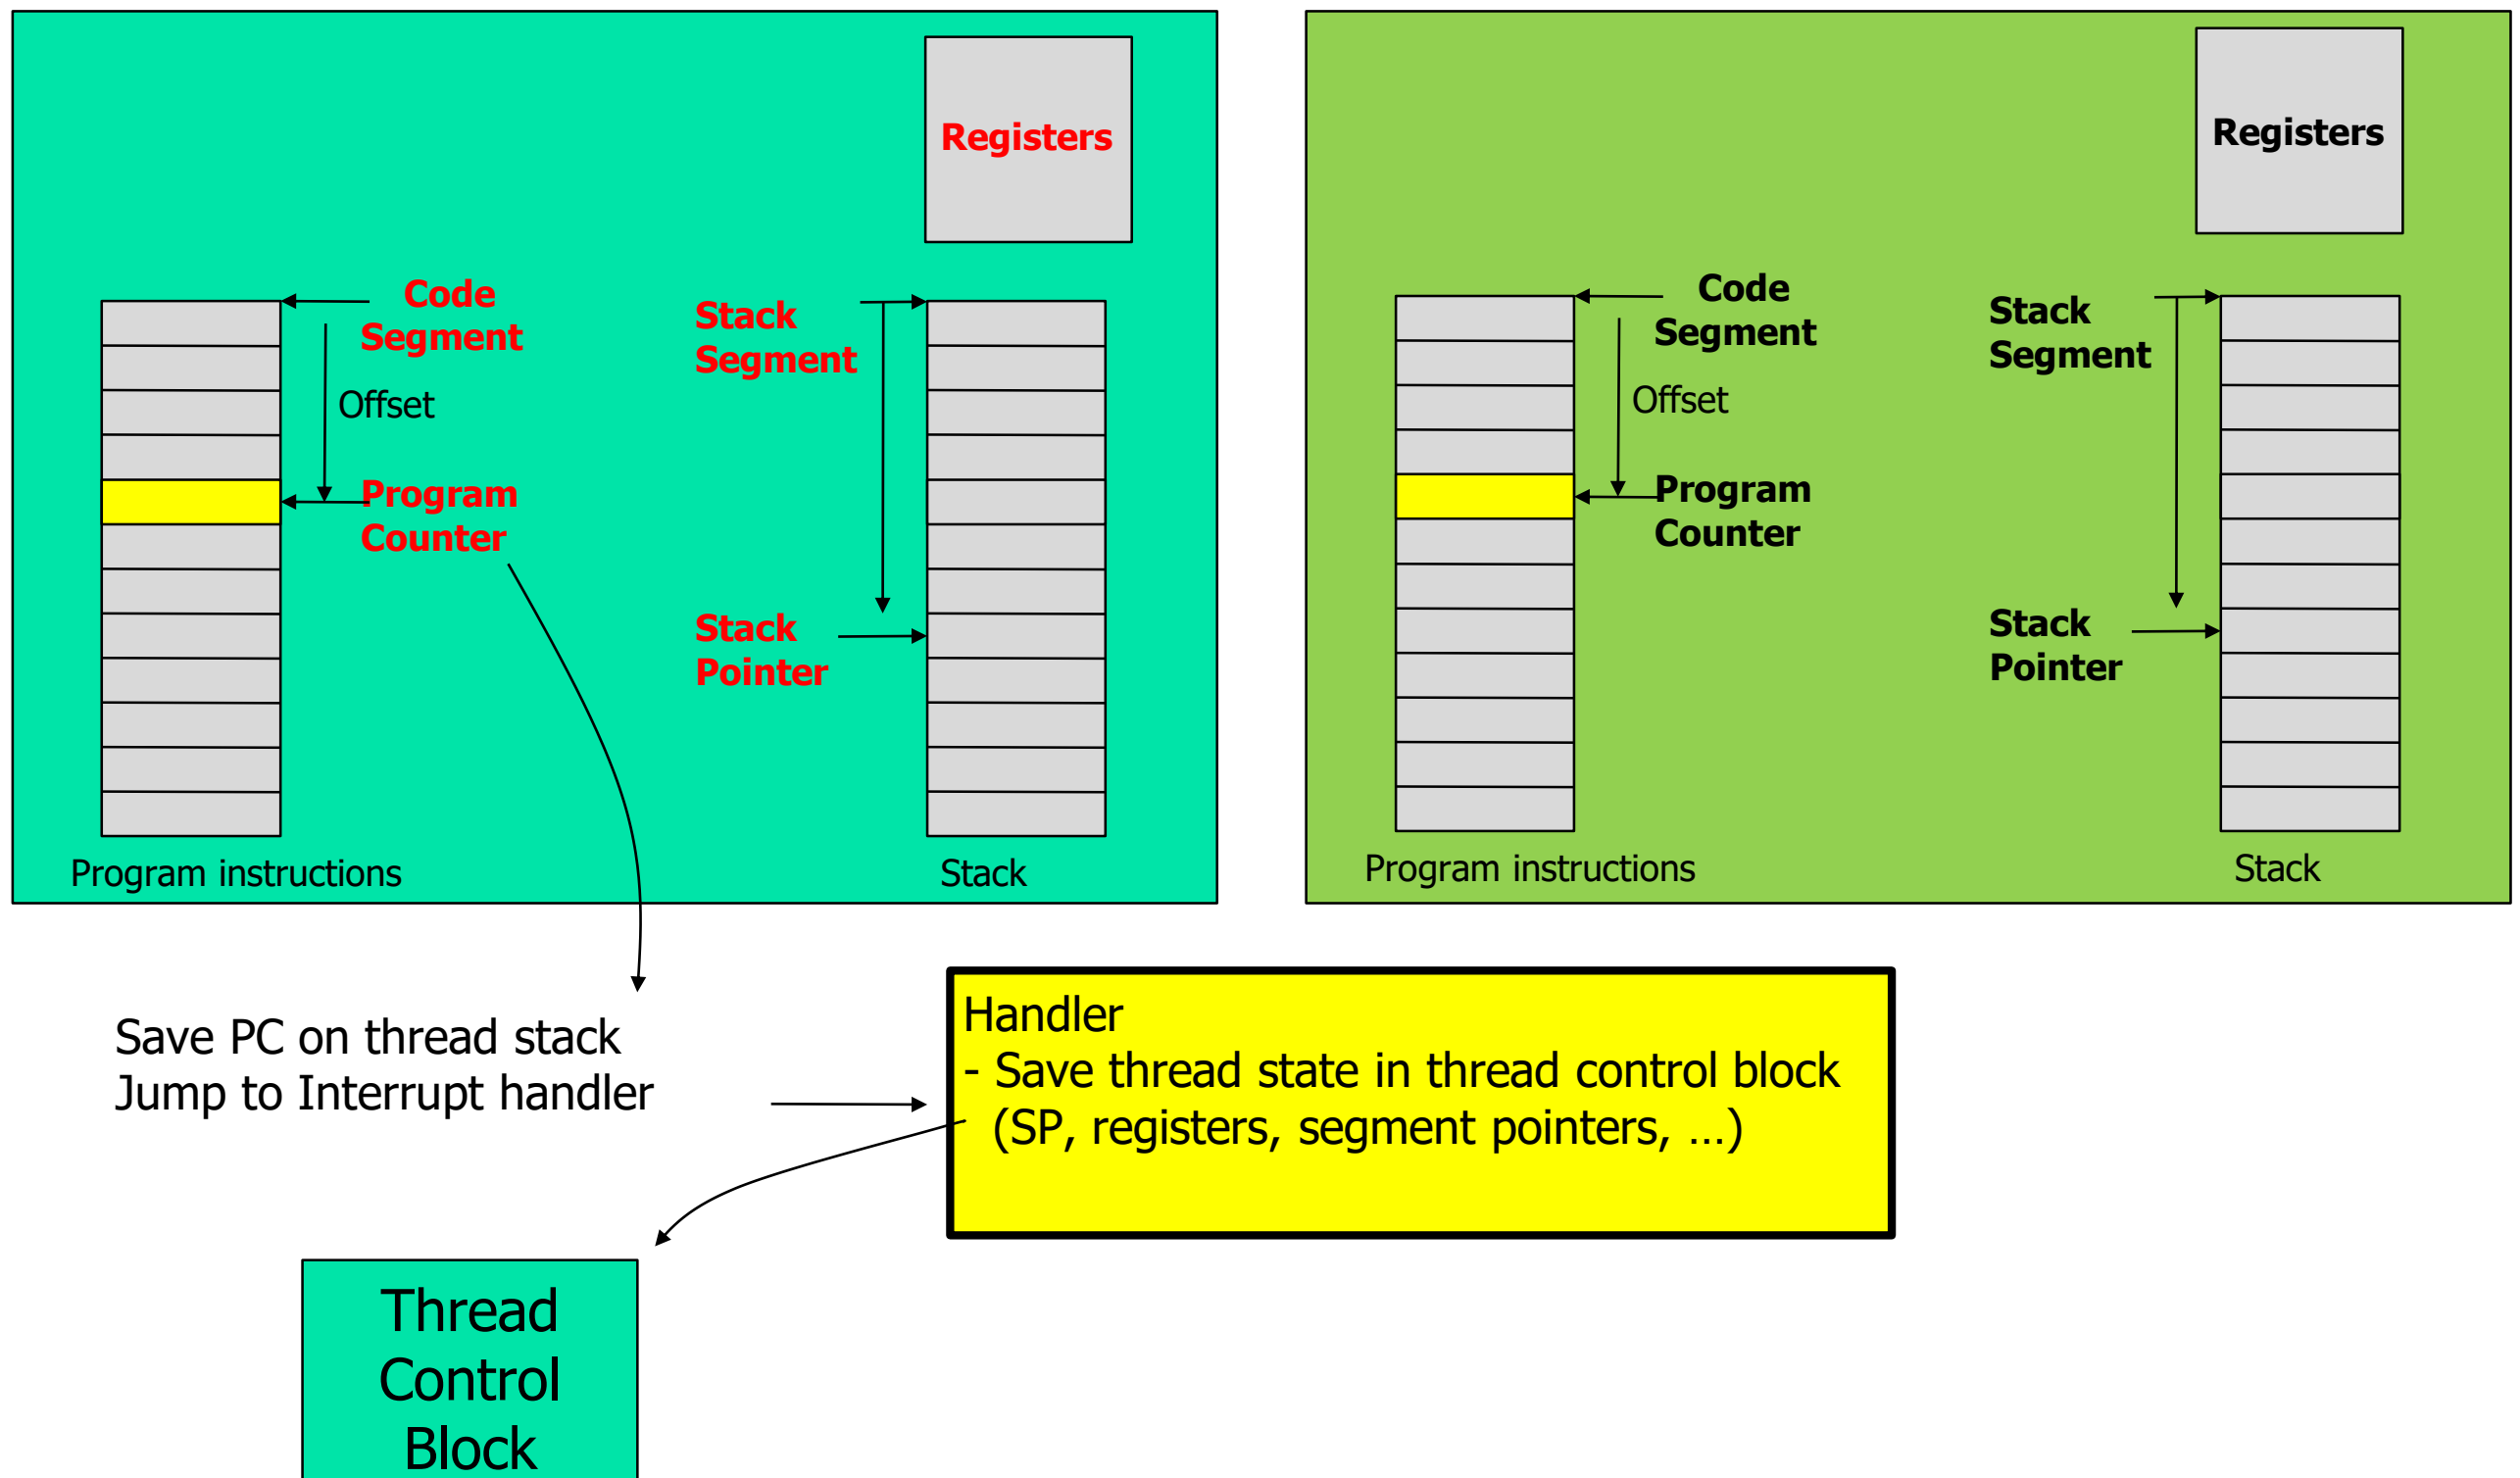

Interrupt

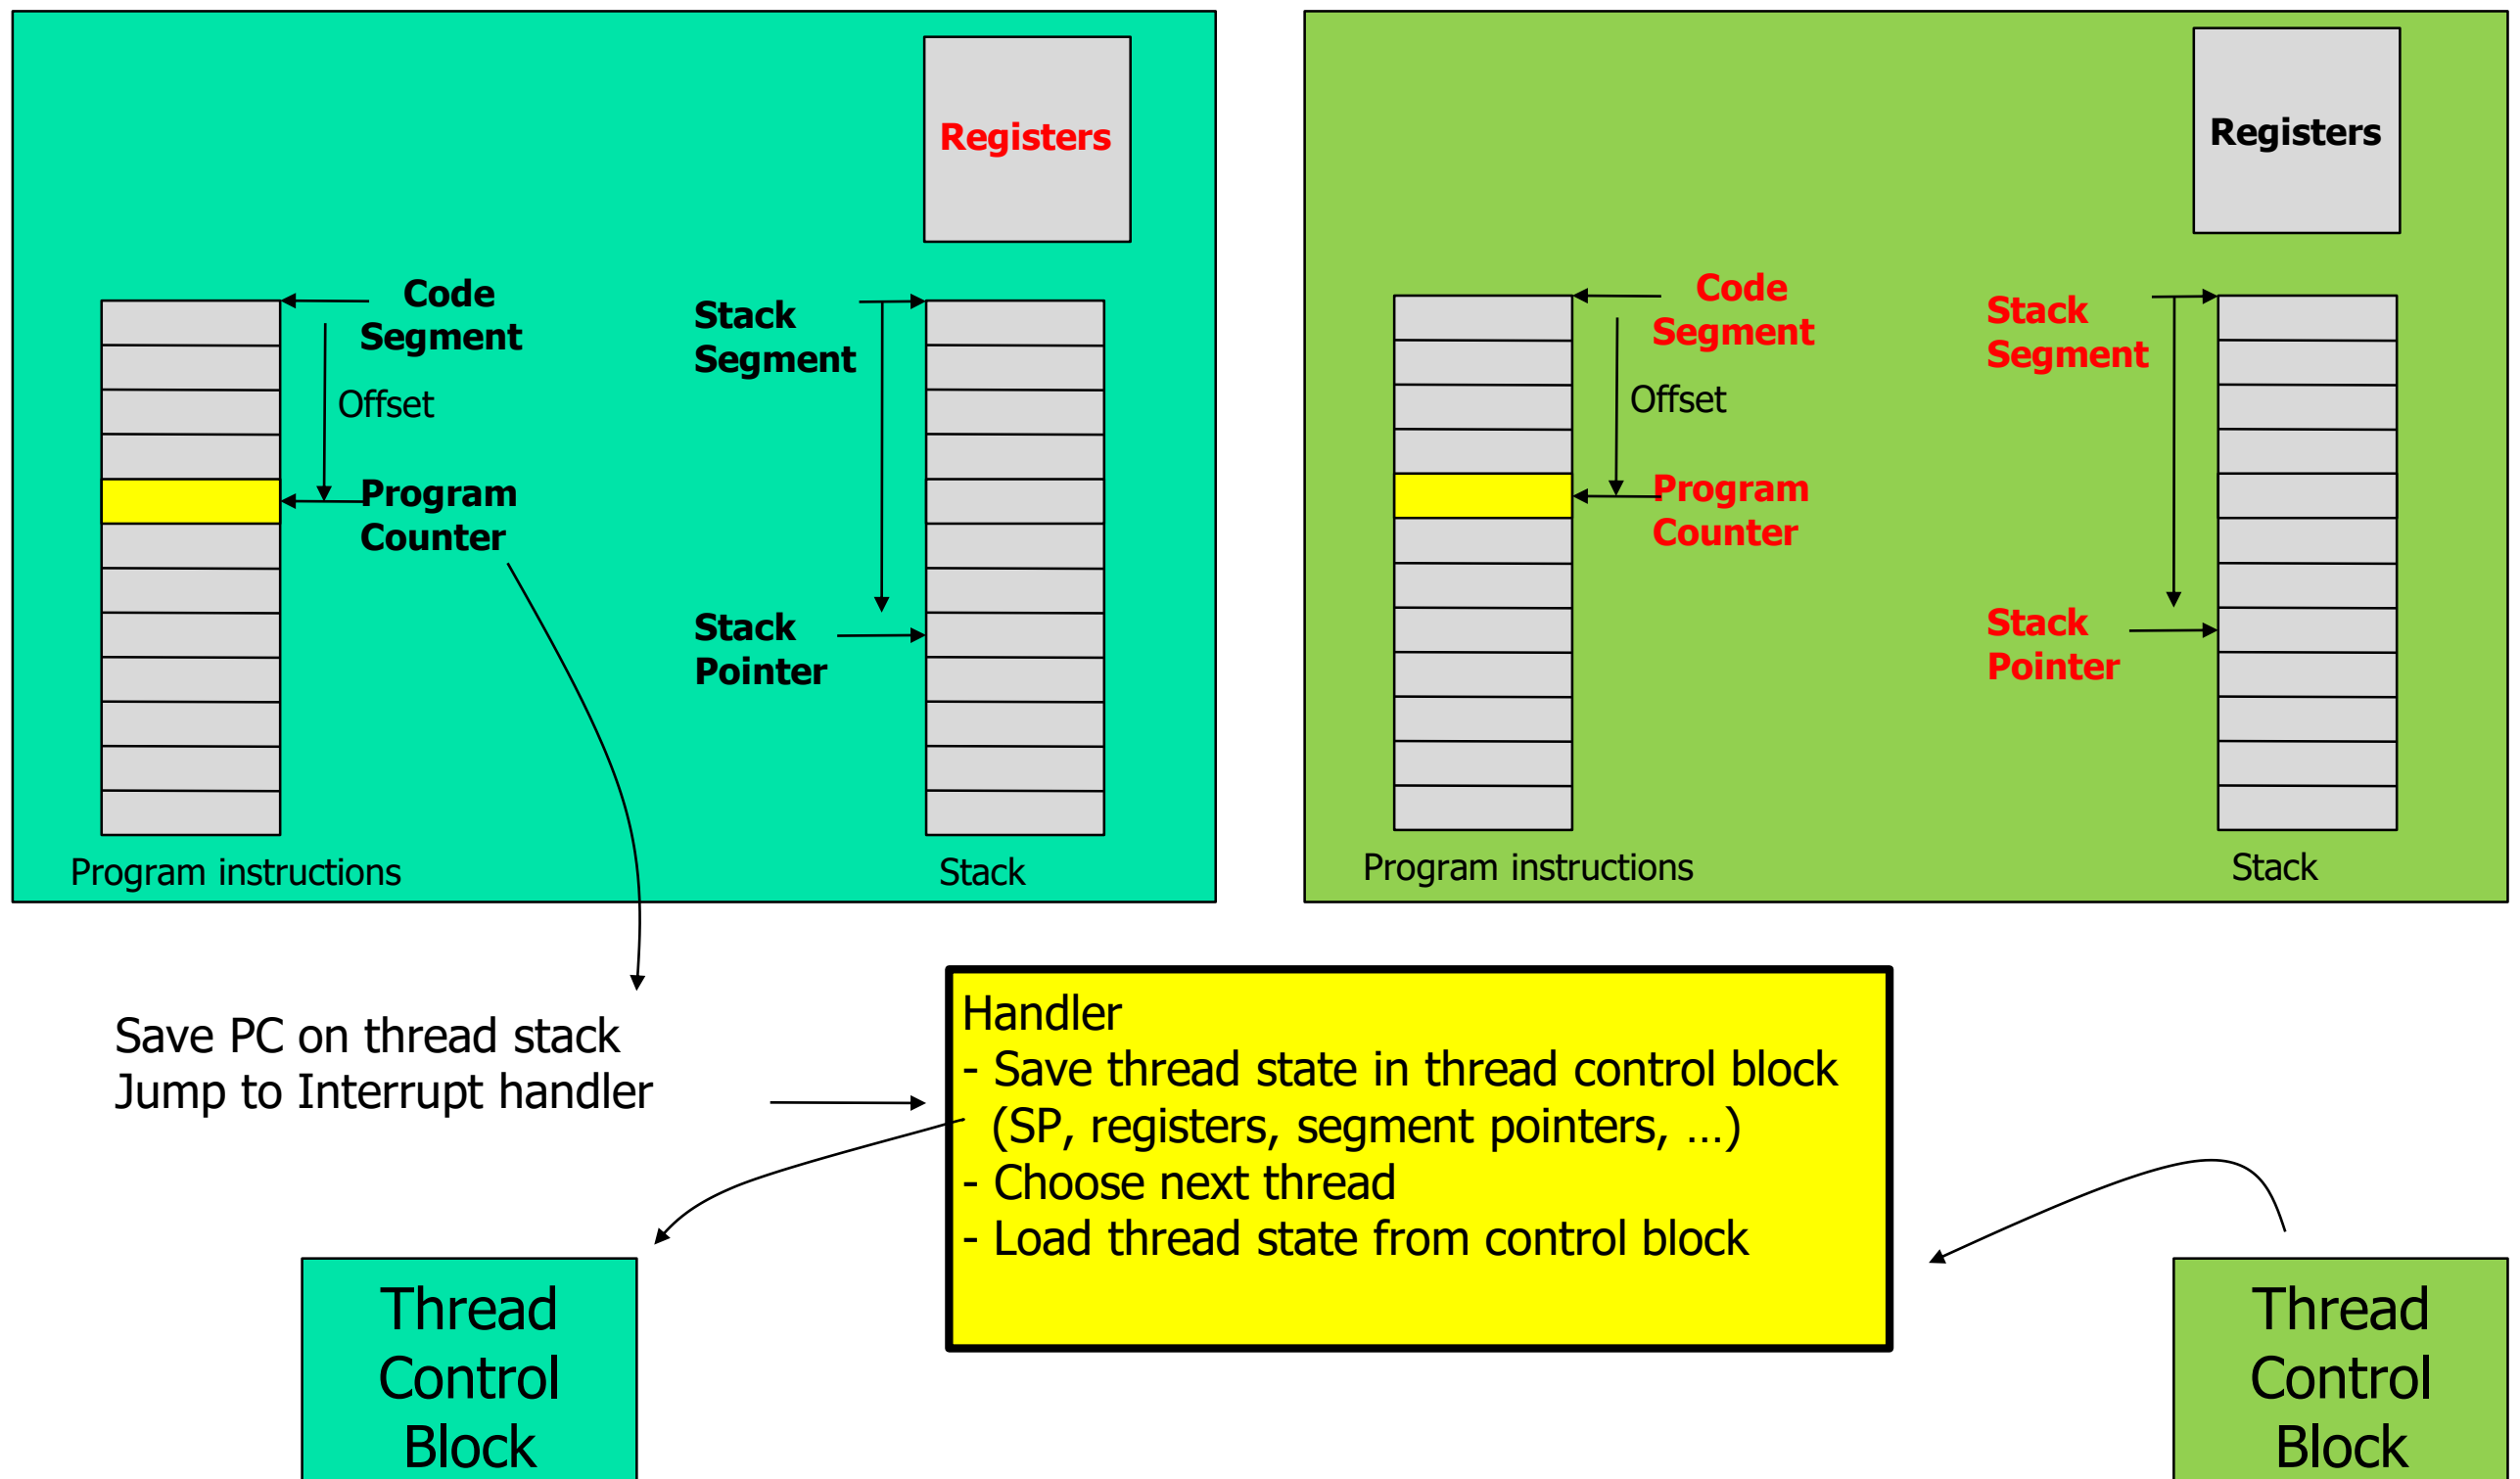

Save PC on thread stack
Jump to Interrupt handler

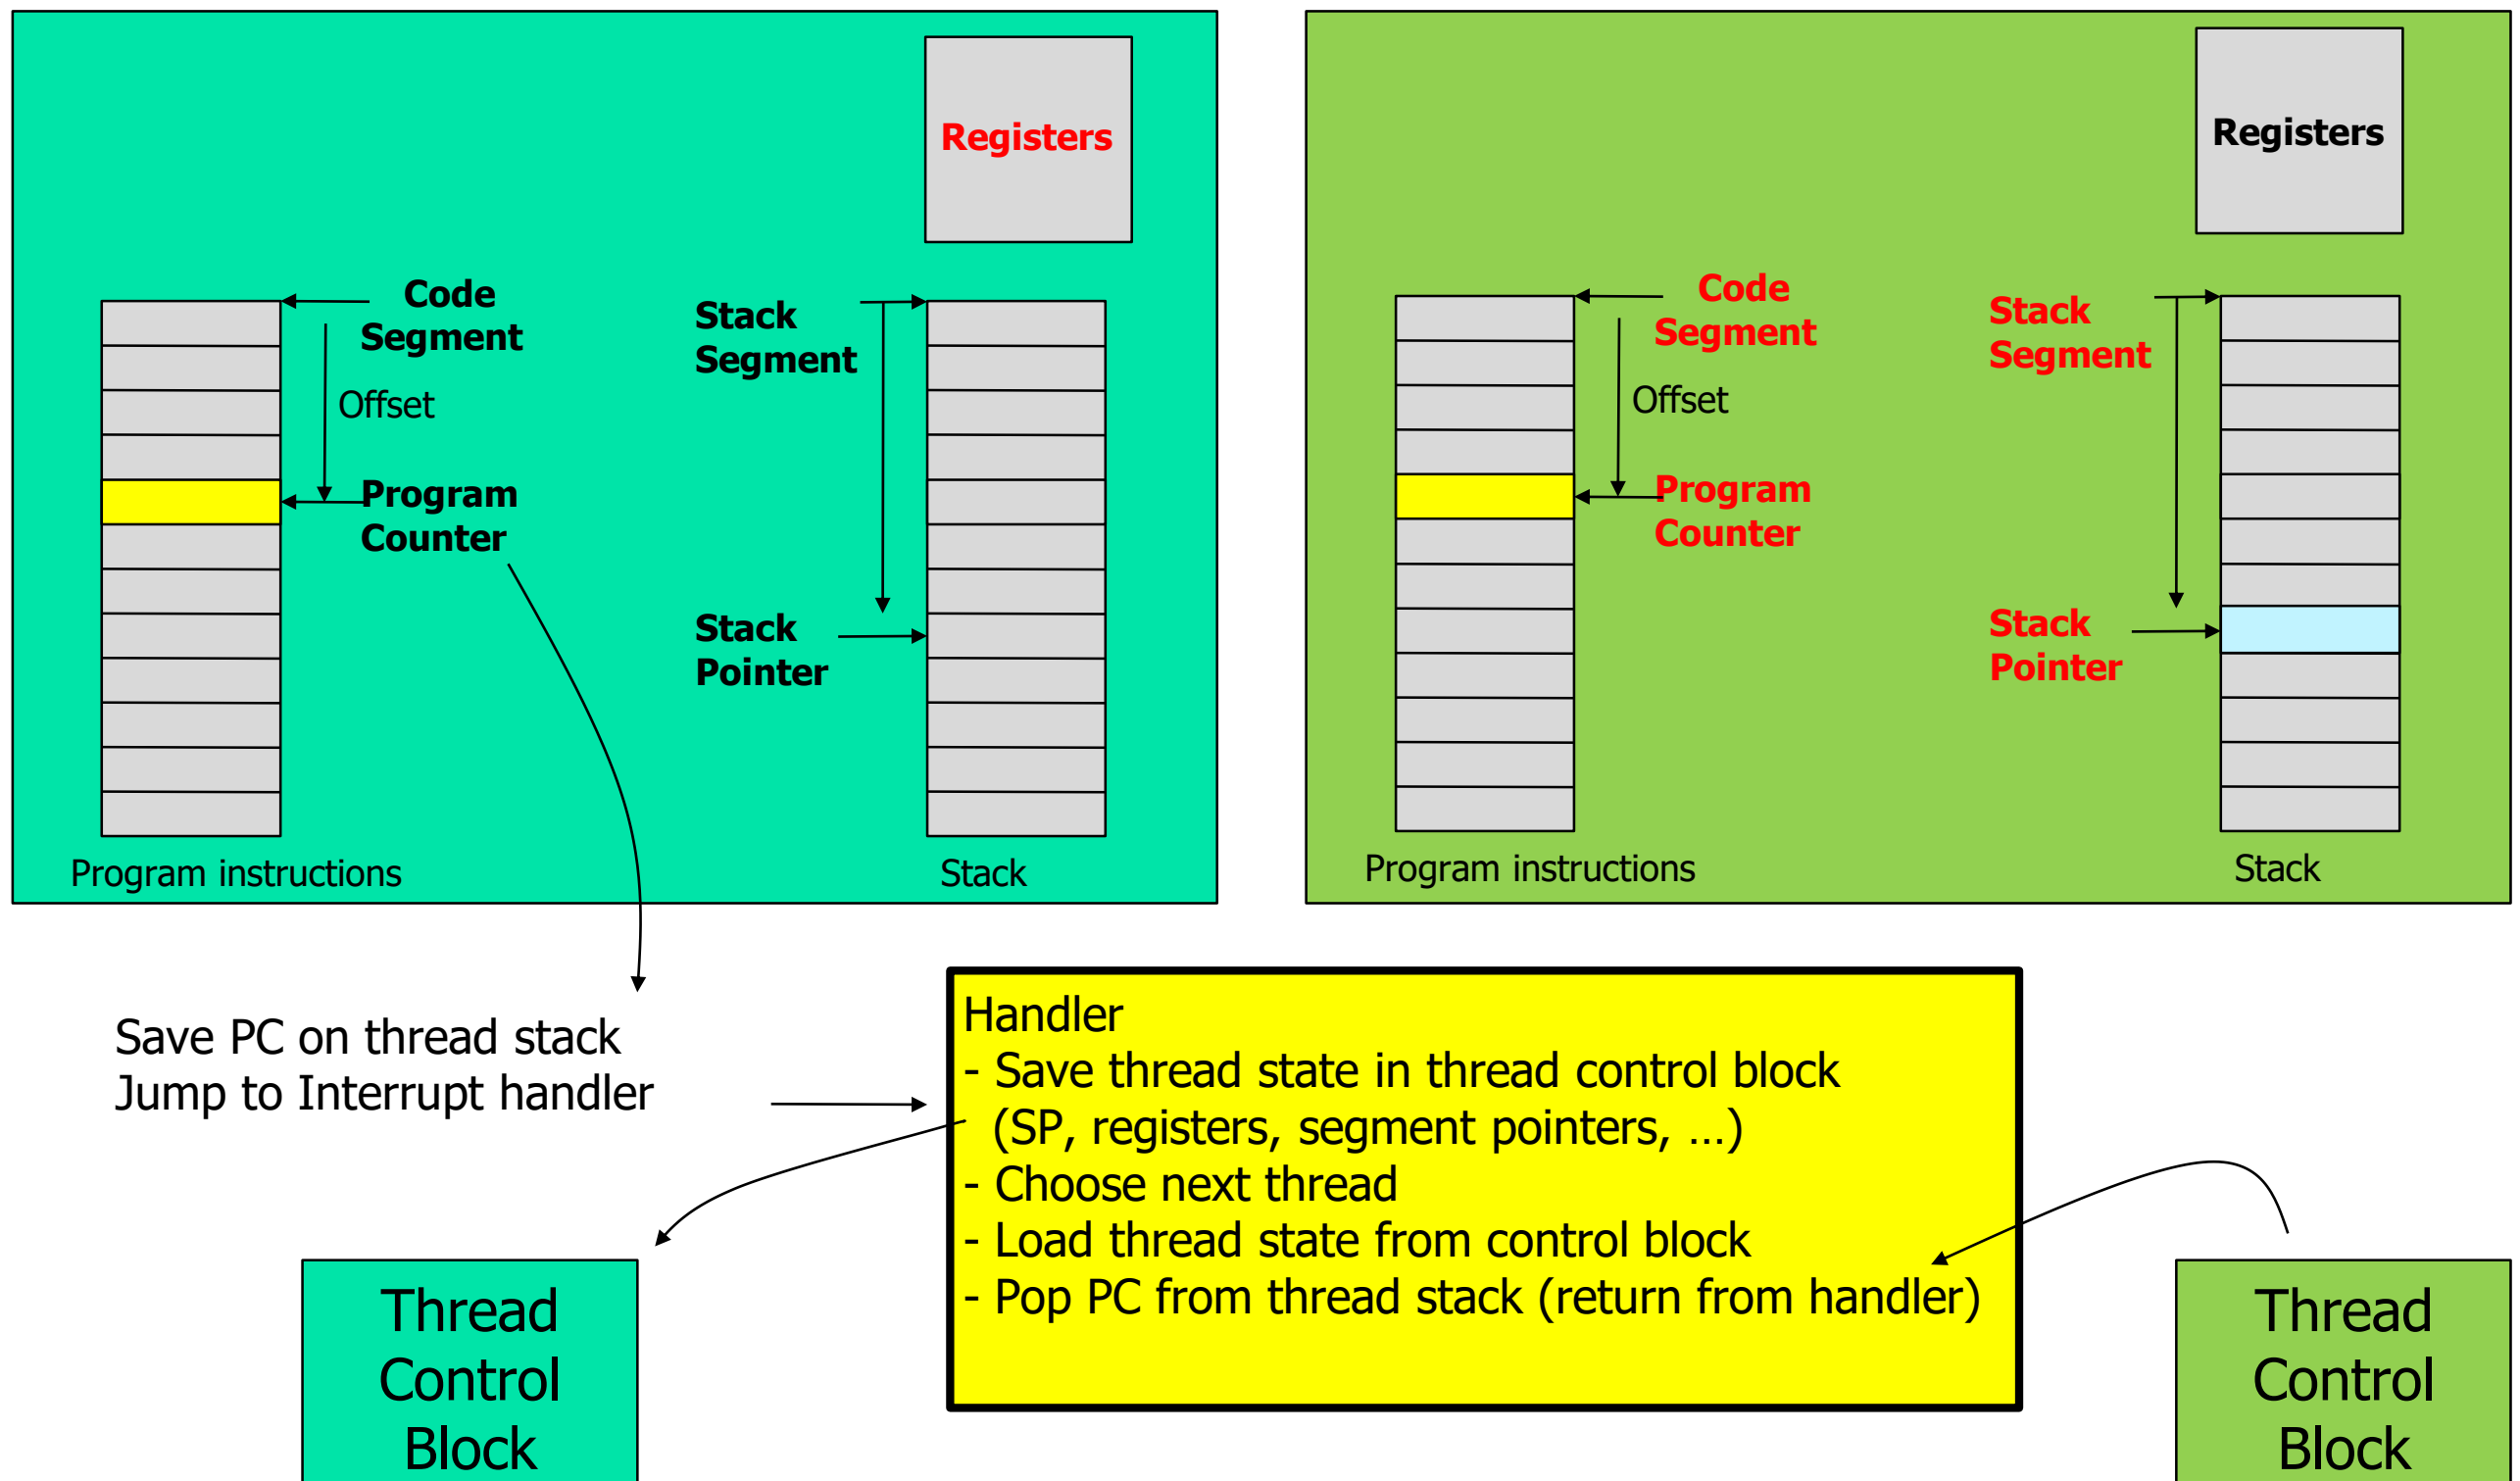

CTX Switch: Interrupt

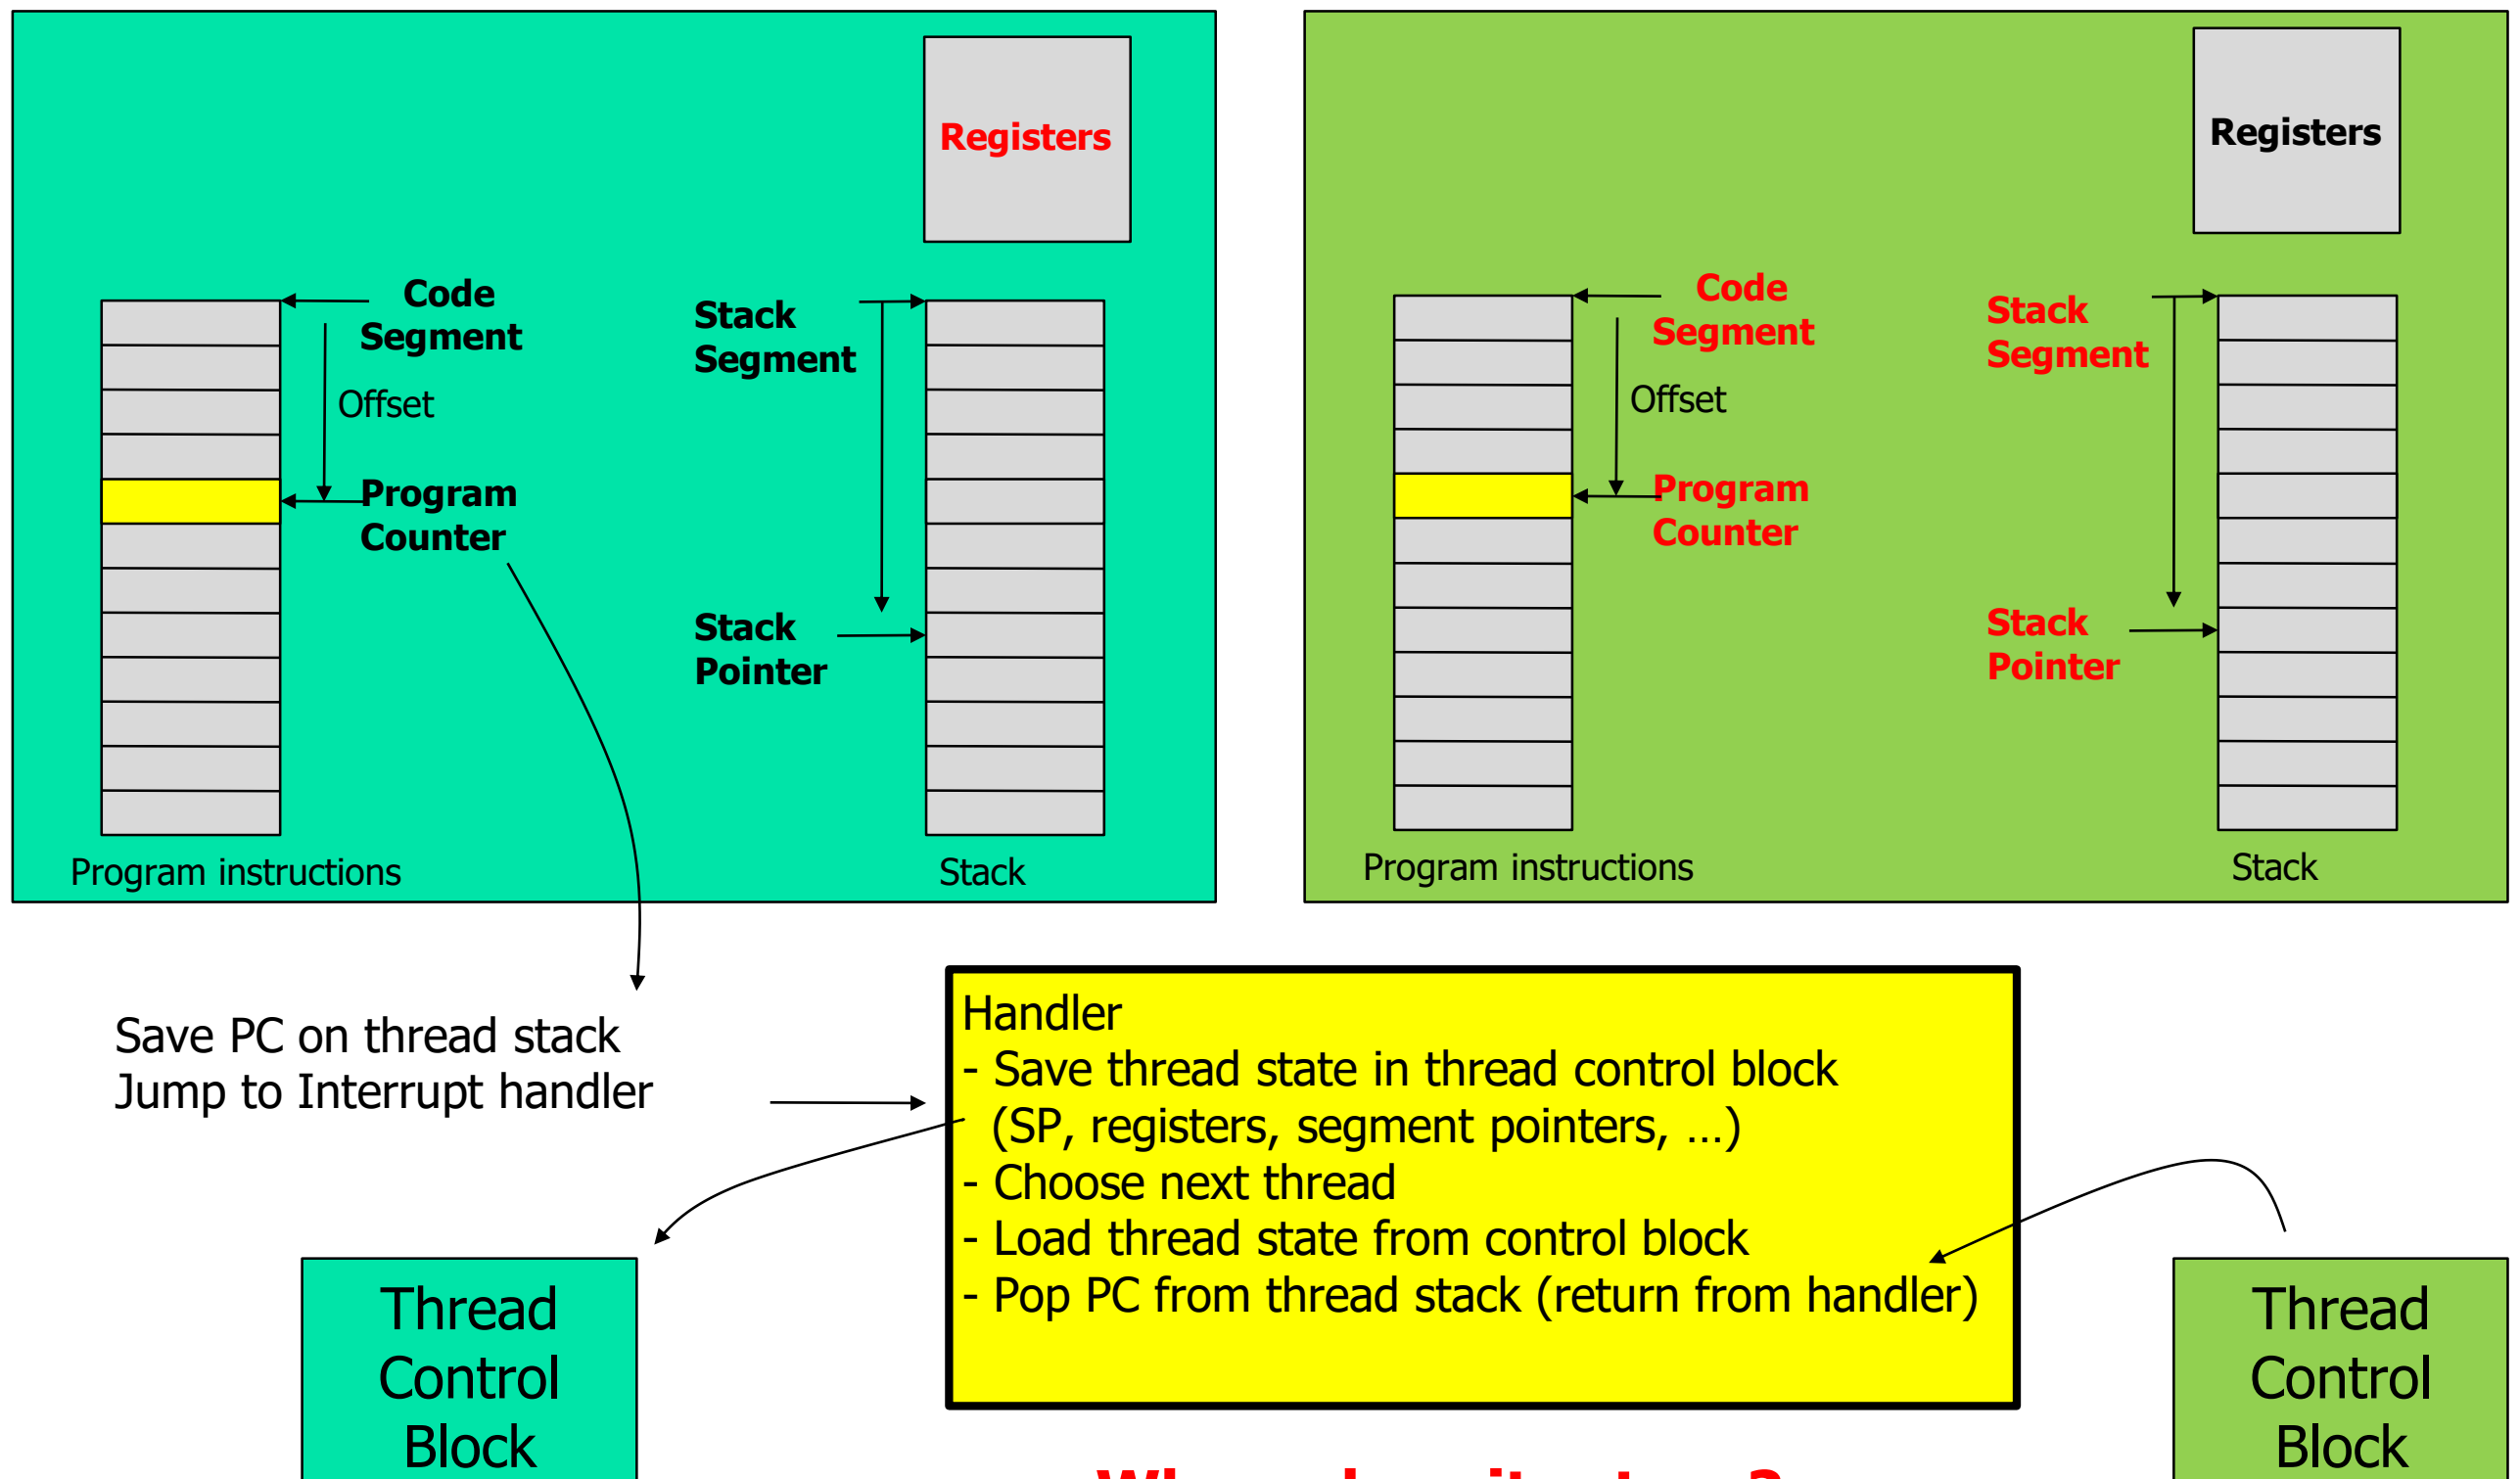

CTX Switch: Interrupt

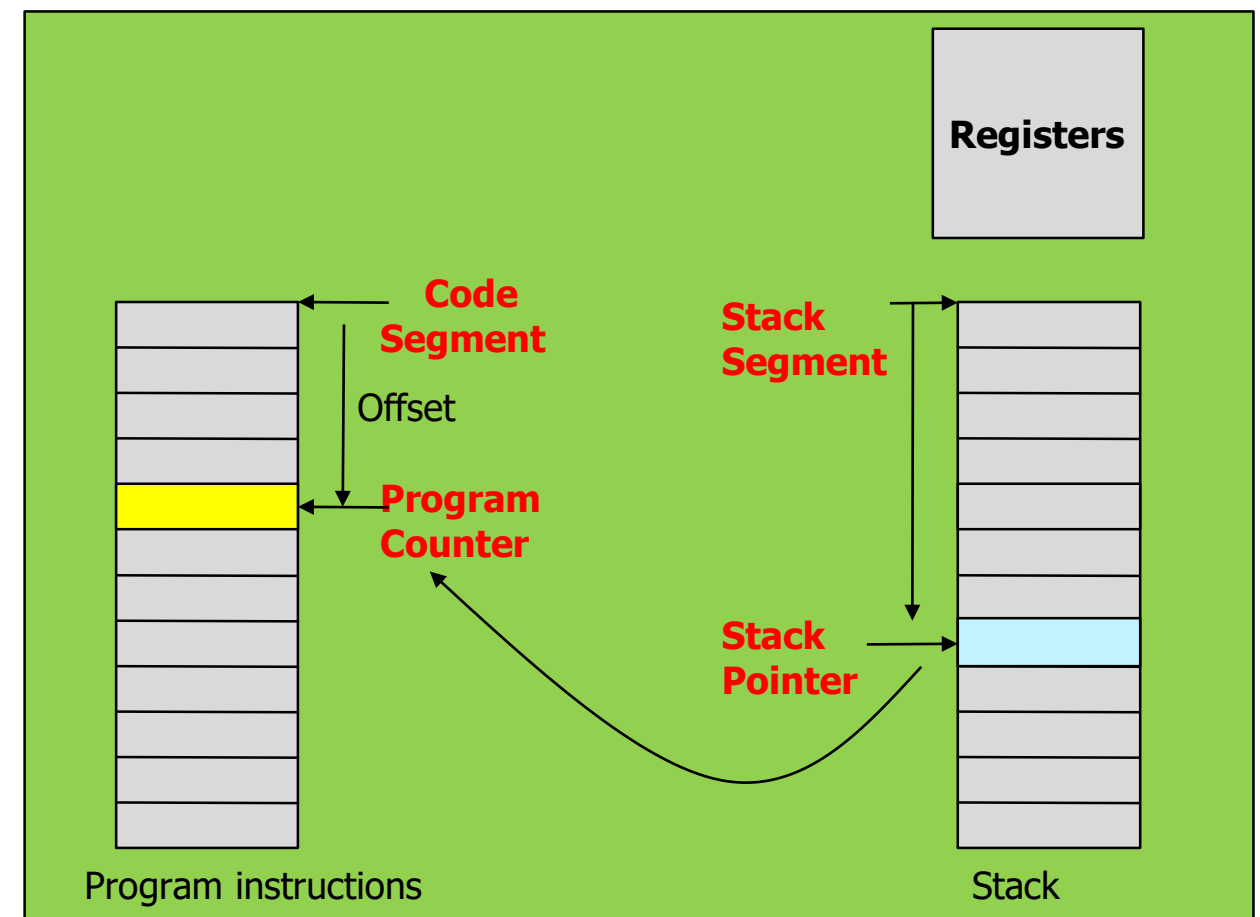

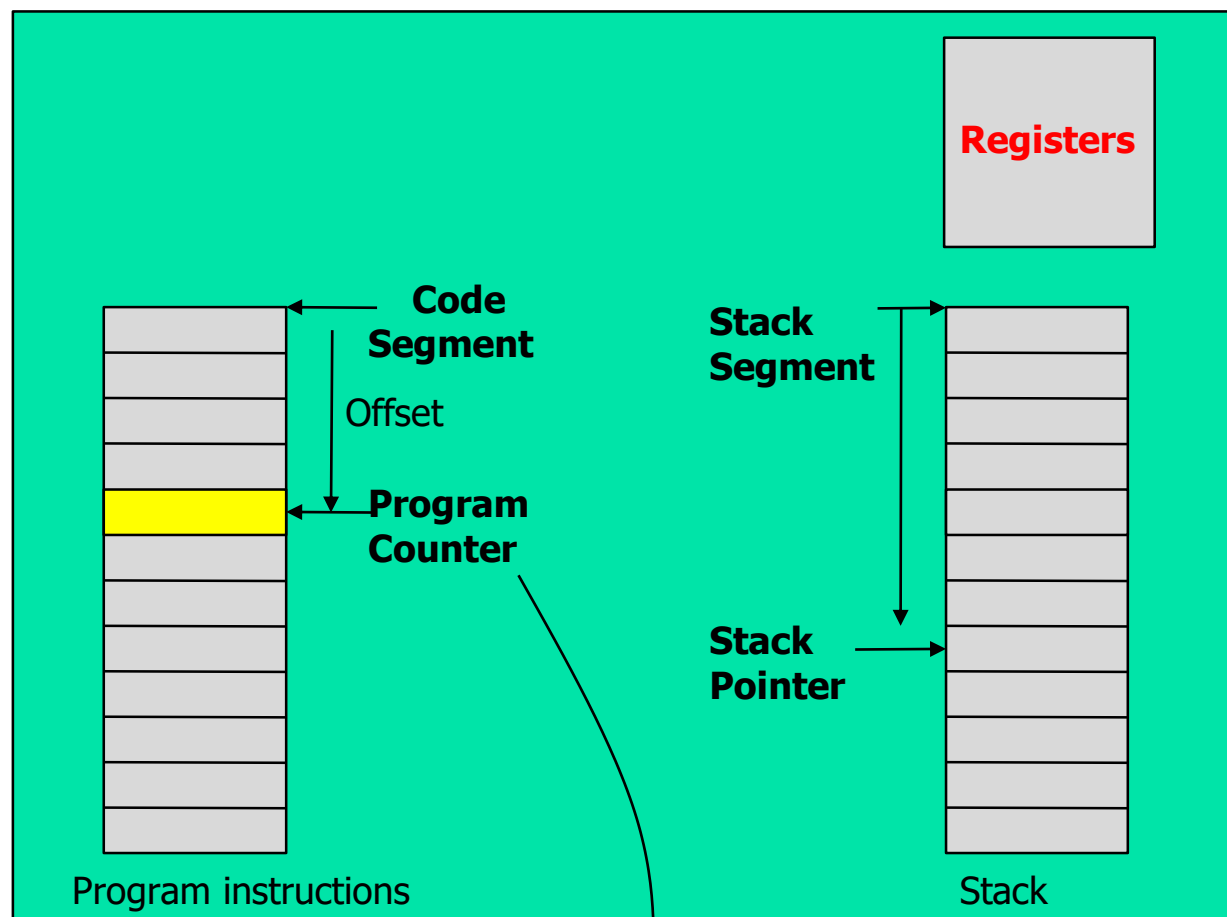

CTX Switch: Interrupt

CTX Switch: Interrupt

CTX Switch: Interrupt

Save PC on thread stack
Jump to Interrupt handler

Thread
Control
Block

Handler

- Save thread state in thread control block (SP, registers, segment pointers, ...)
- Choose next thread
- Load thread state from control block
- Pop PC from thread stack (return from handler)

Thread
Control
Block

Where does it return?

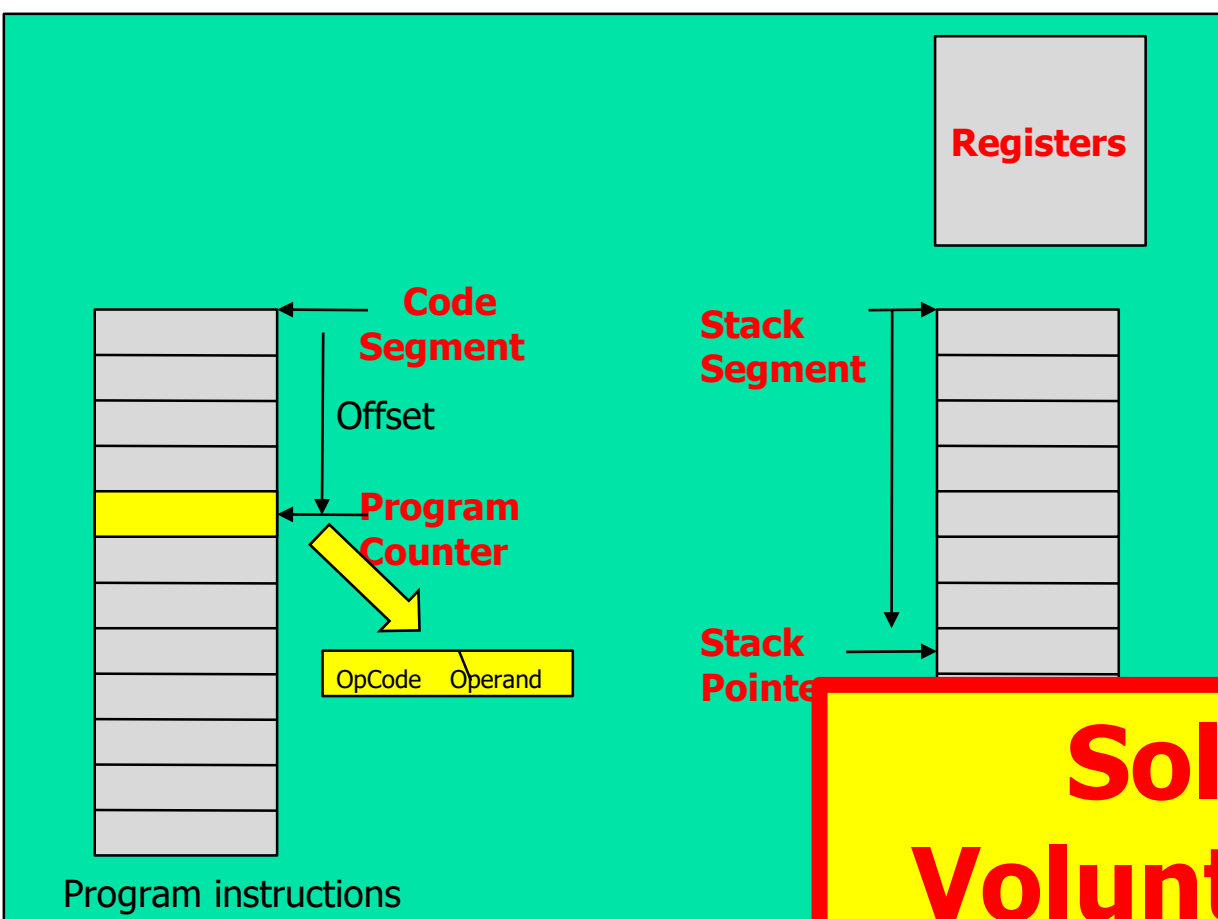

What are some examples of context switches due to interrupts?

- **Clock Interrupt:** Task exceeds its time slice
- **I/O Interrupt:** Waiting processes may be preempted
- **Memory Fault:** CPU attempts to access a virtual memory address that is not in main memory. OS may resume execution of another process while retrieving the block, then moves process to ready state.

Thread Context Switch

Note: In **thread** context switches, heap is not switched!

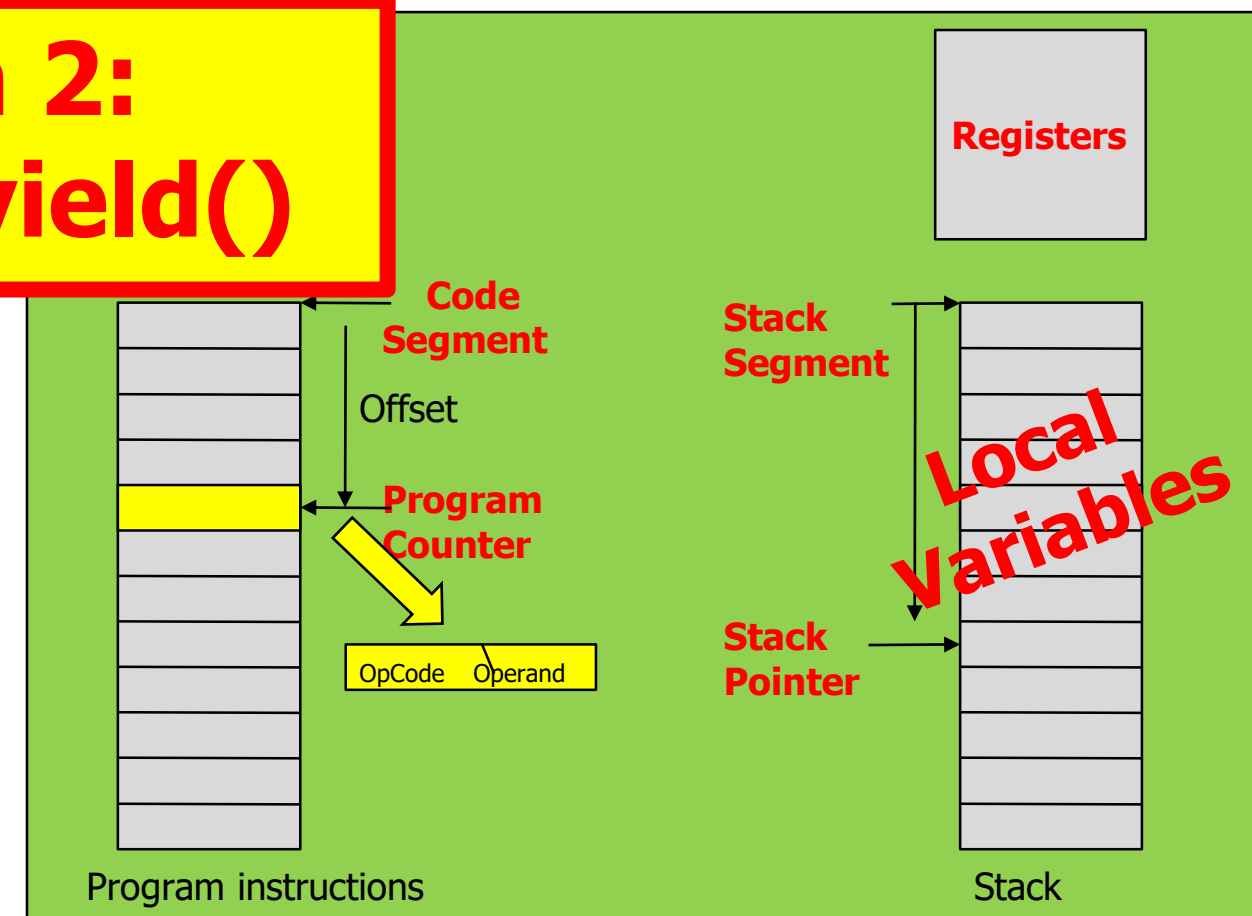

**Load State
(Context)**

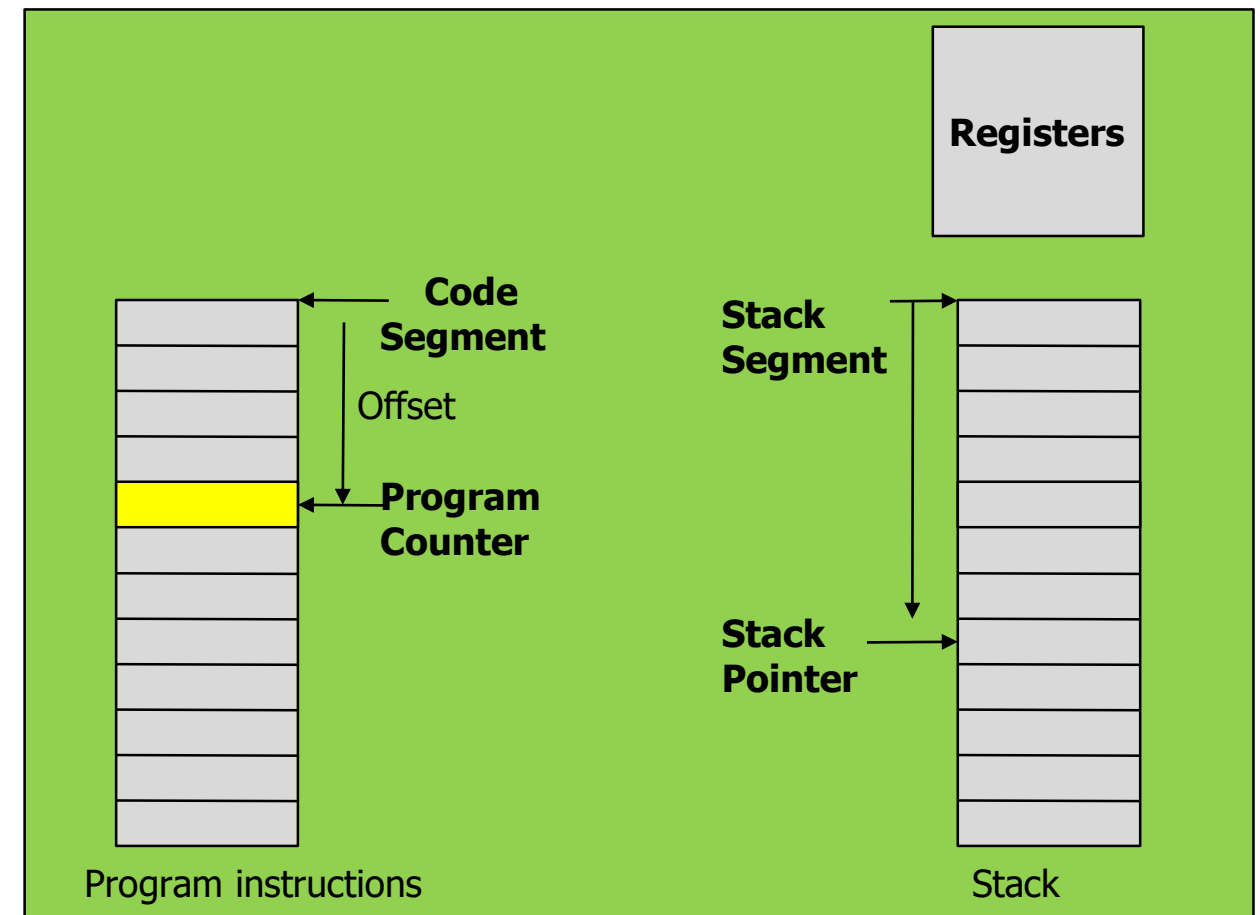

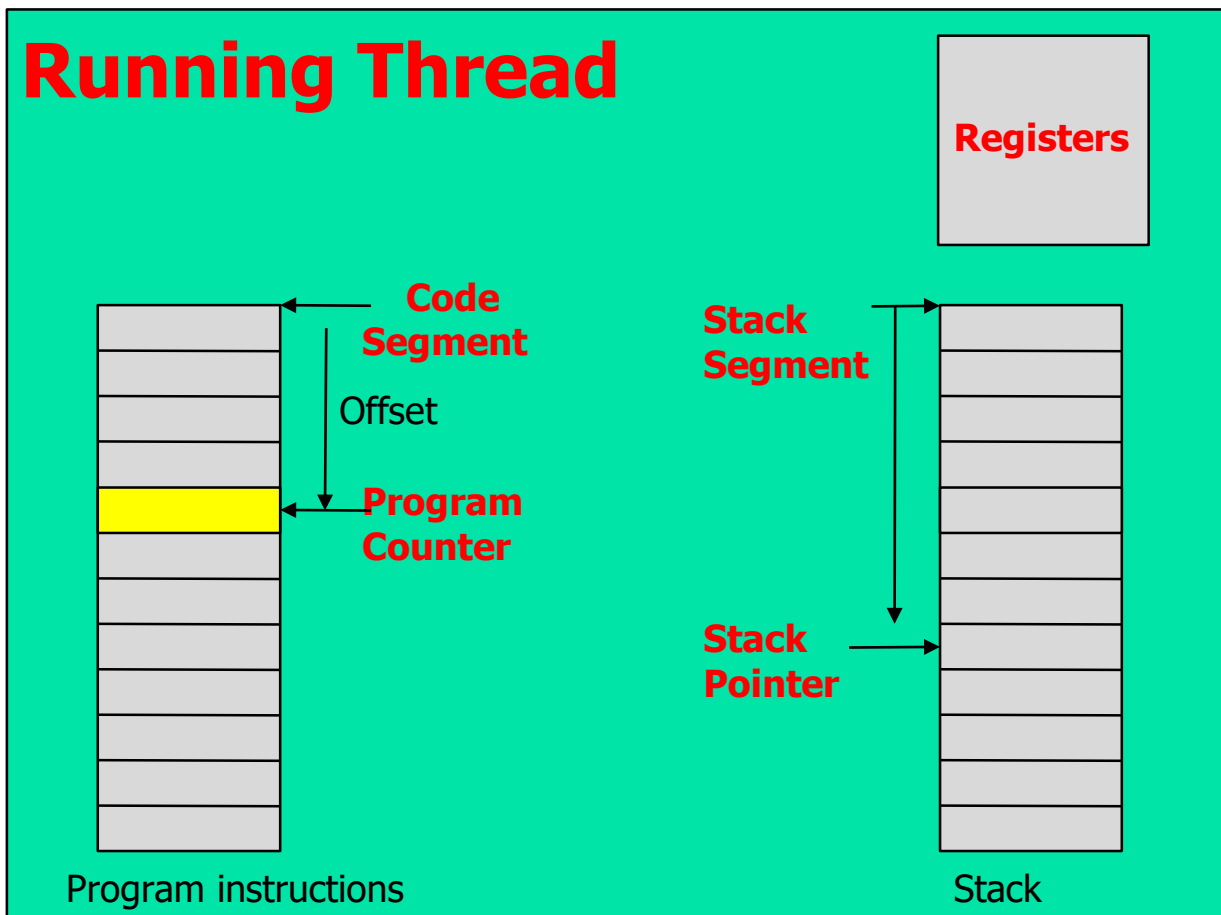

**Solution 2:
Voluntary yield()**

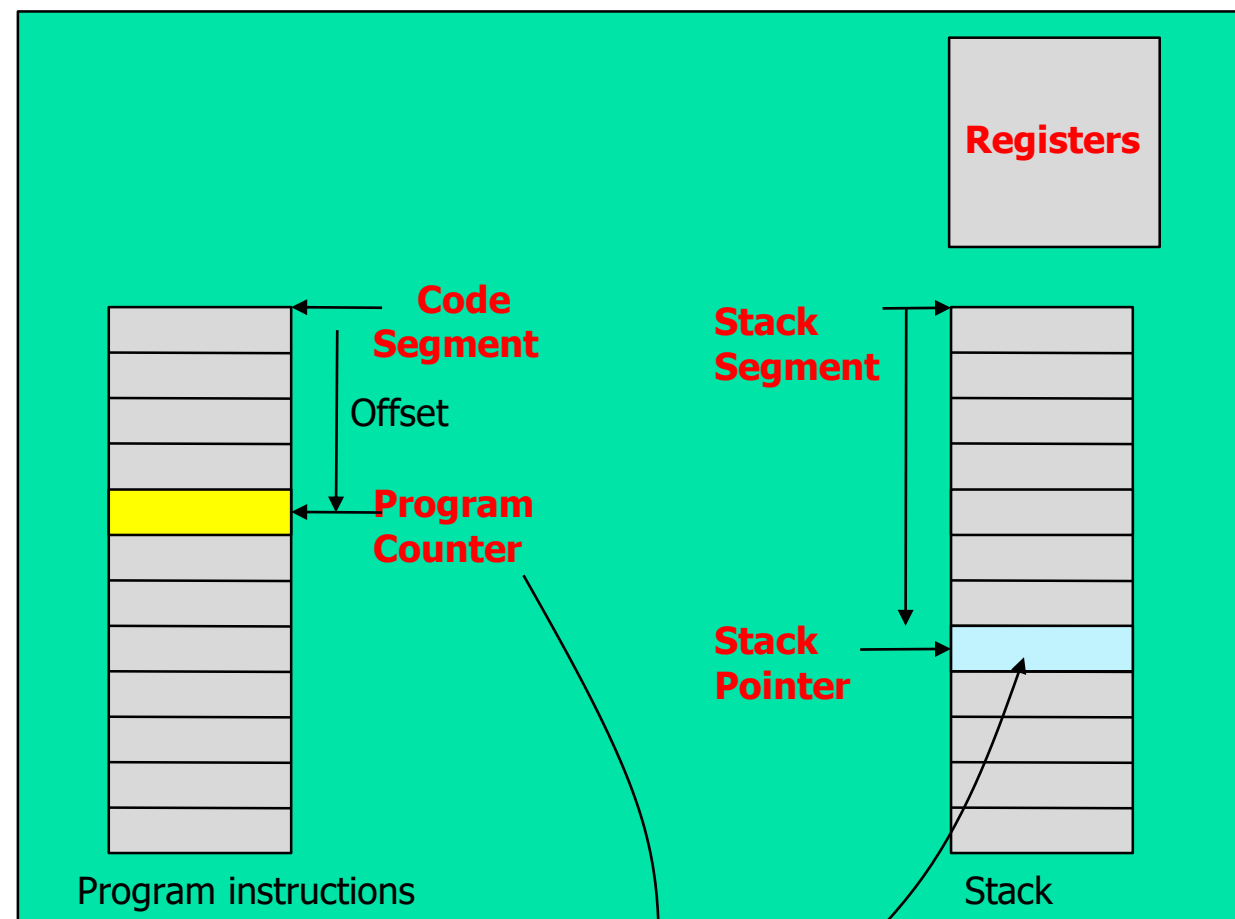

**Save State
(Context)**

CTX Switch: Yield

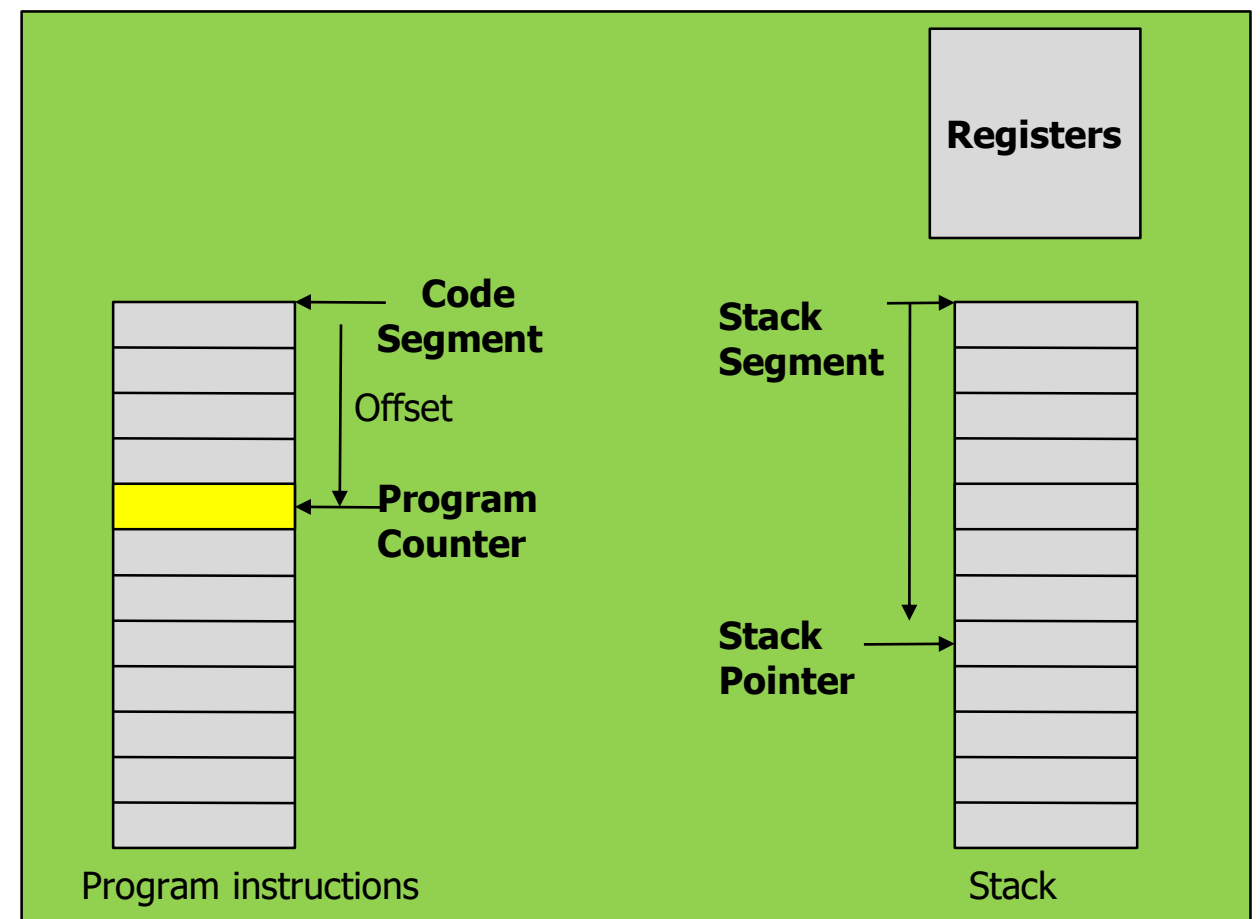

CTX Switch: Yield

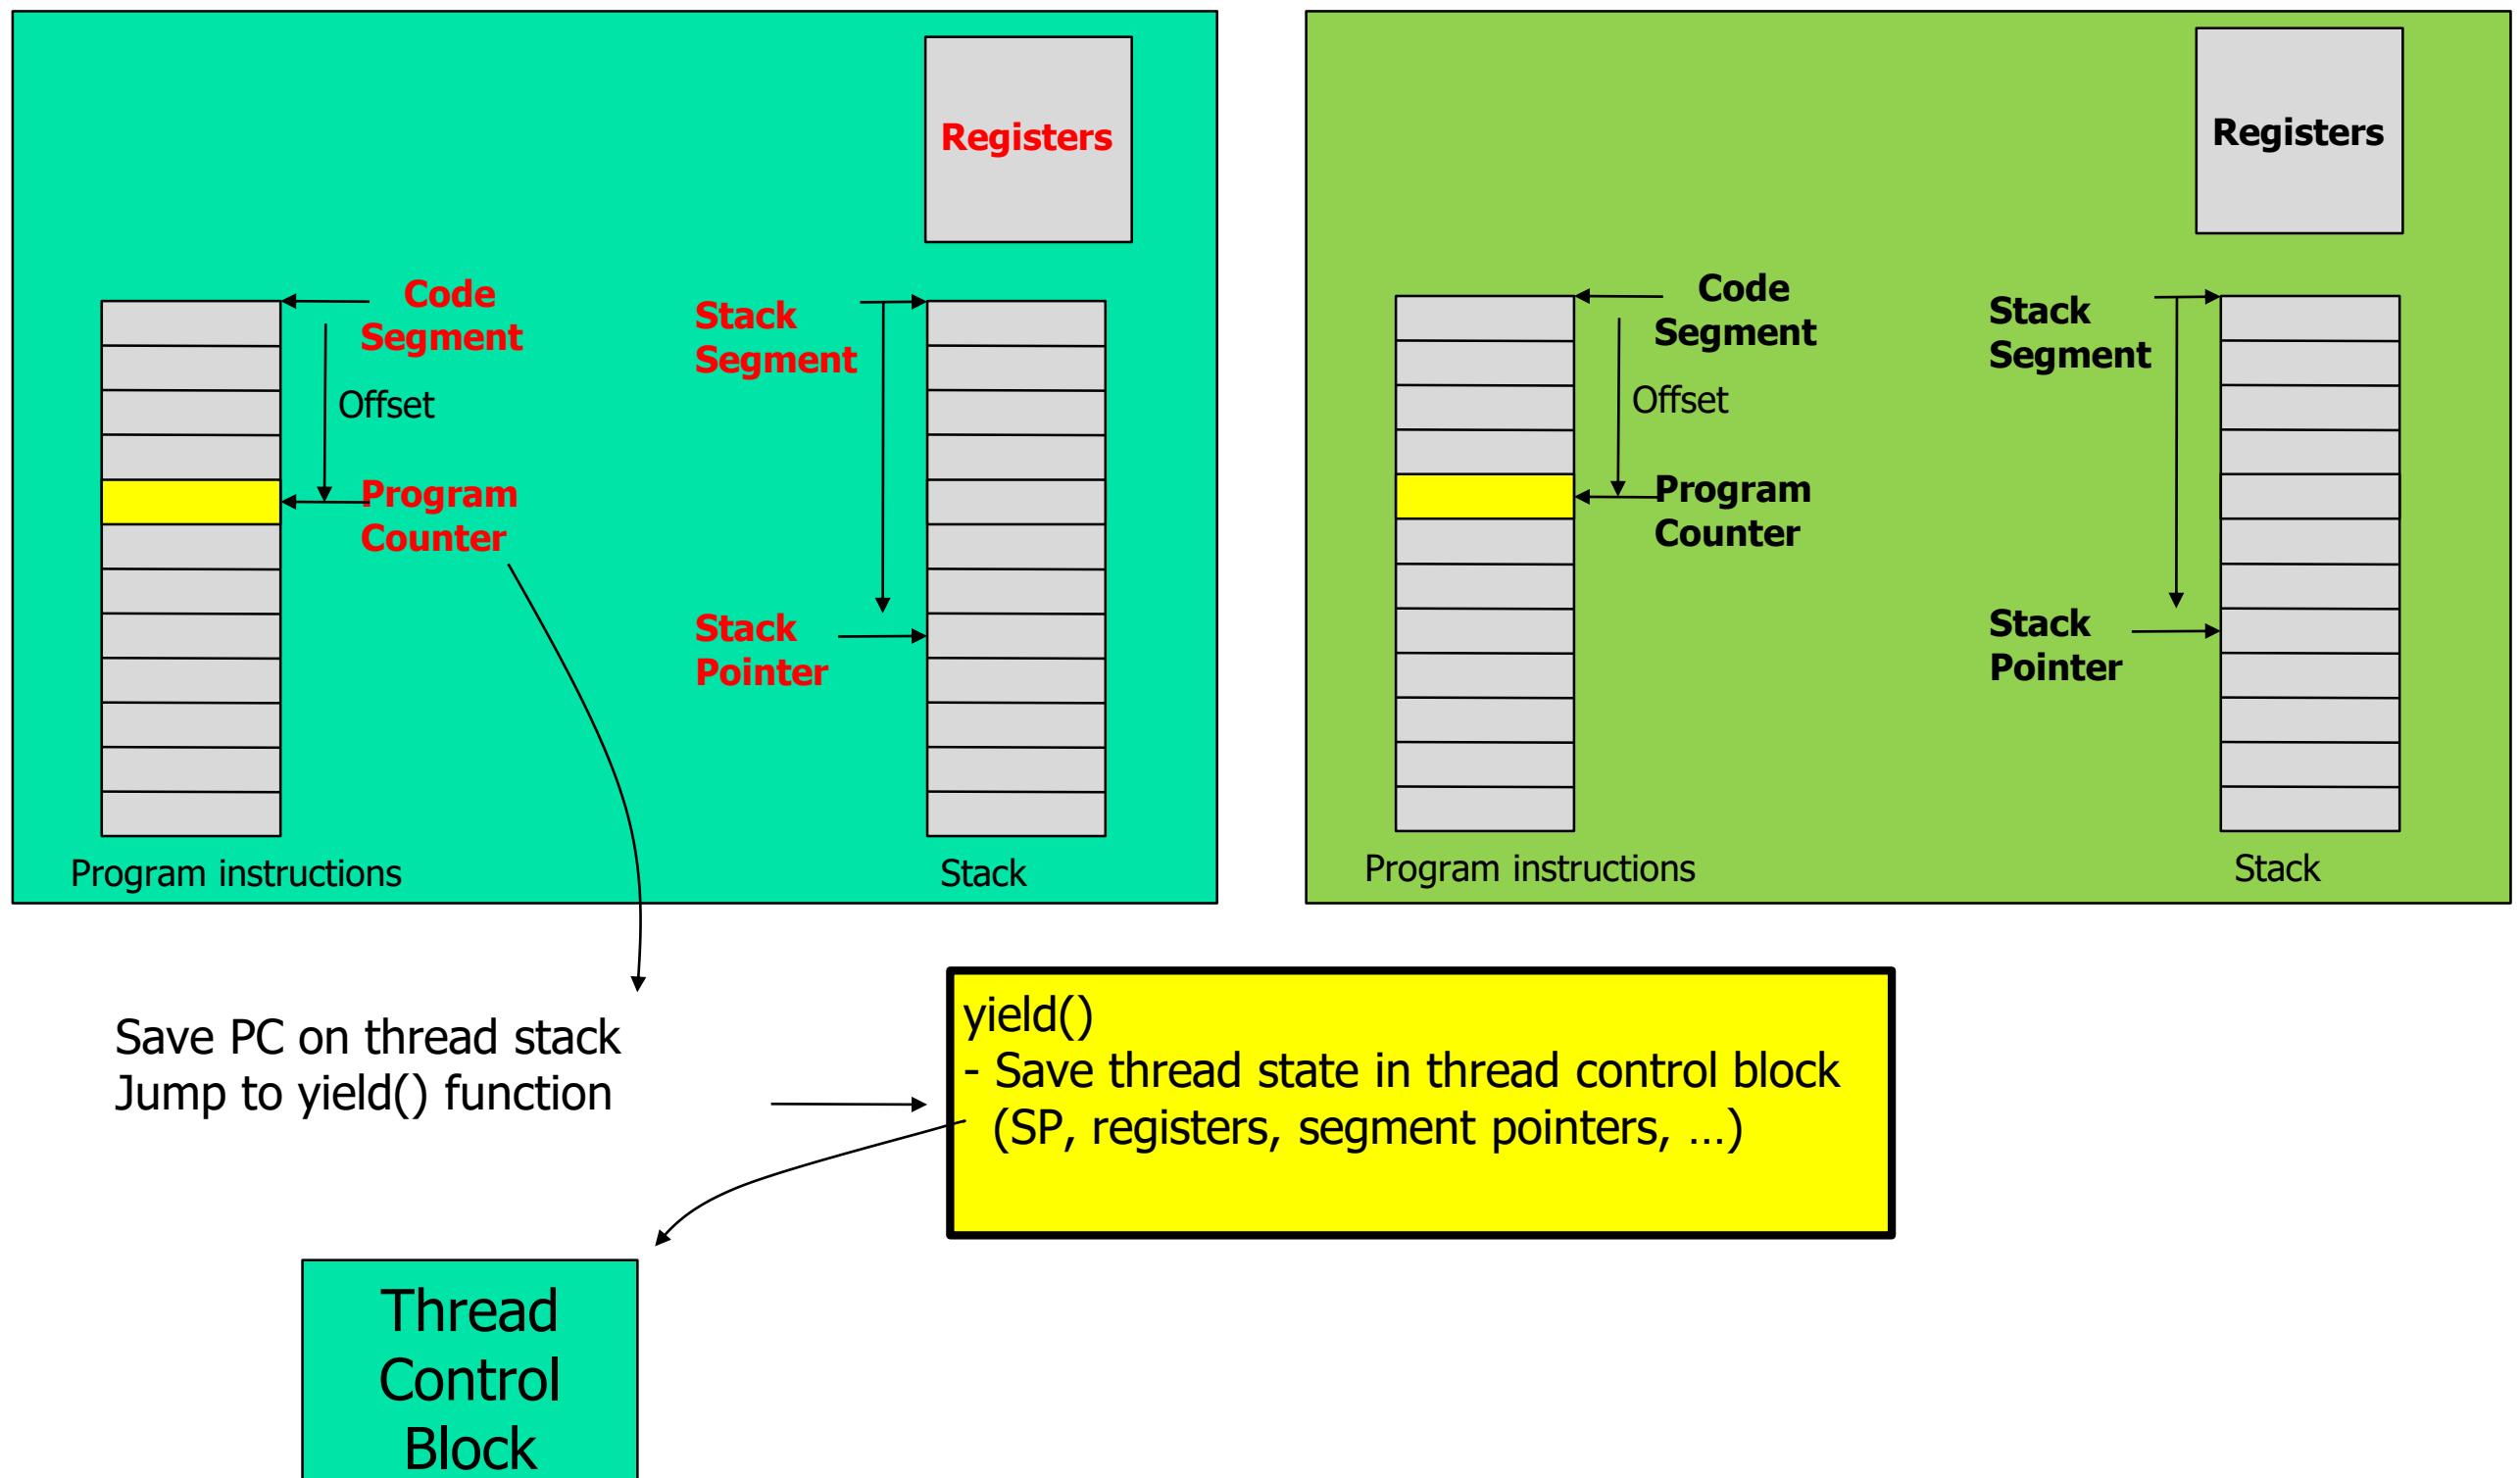

yield()

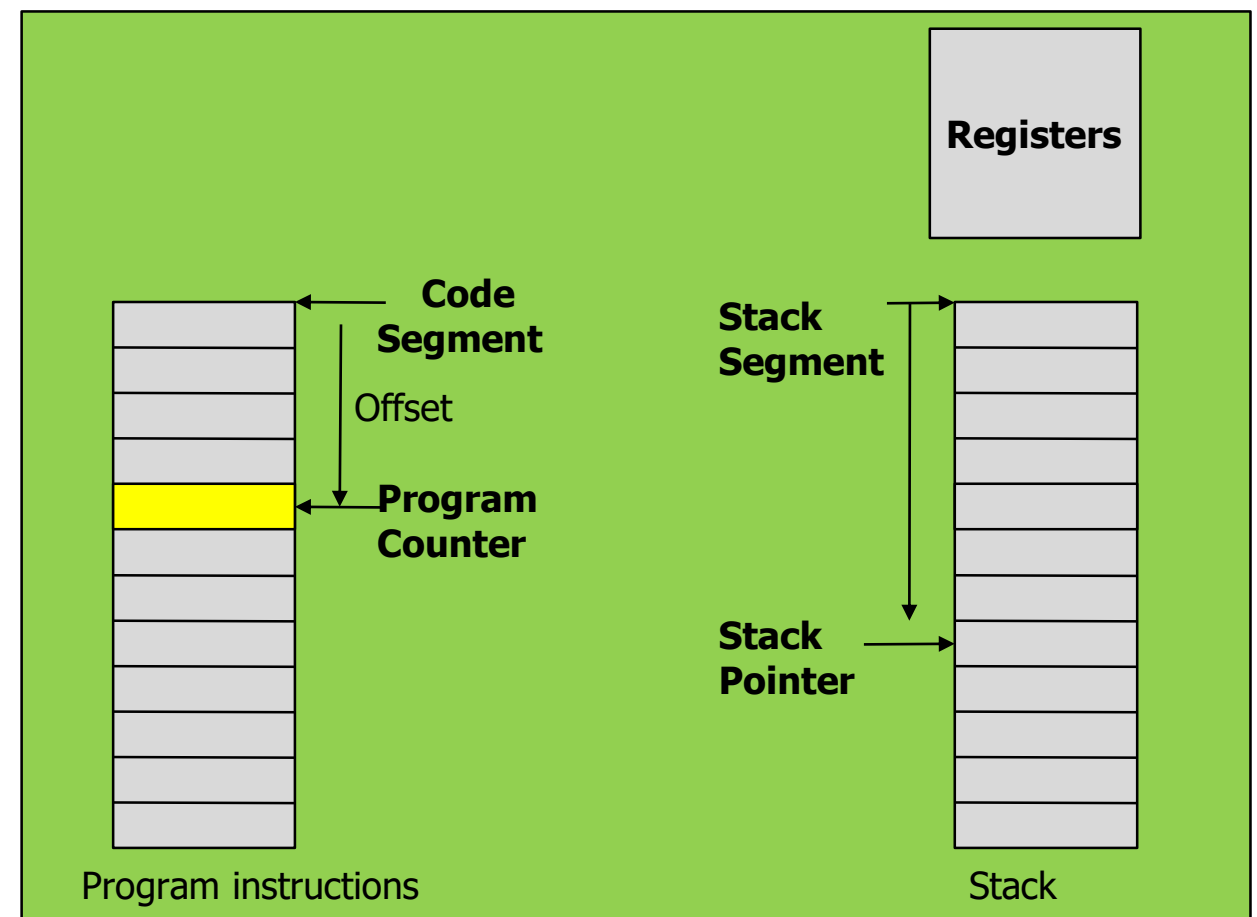

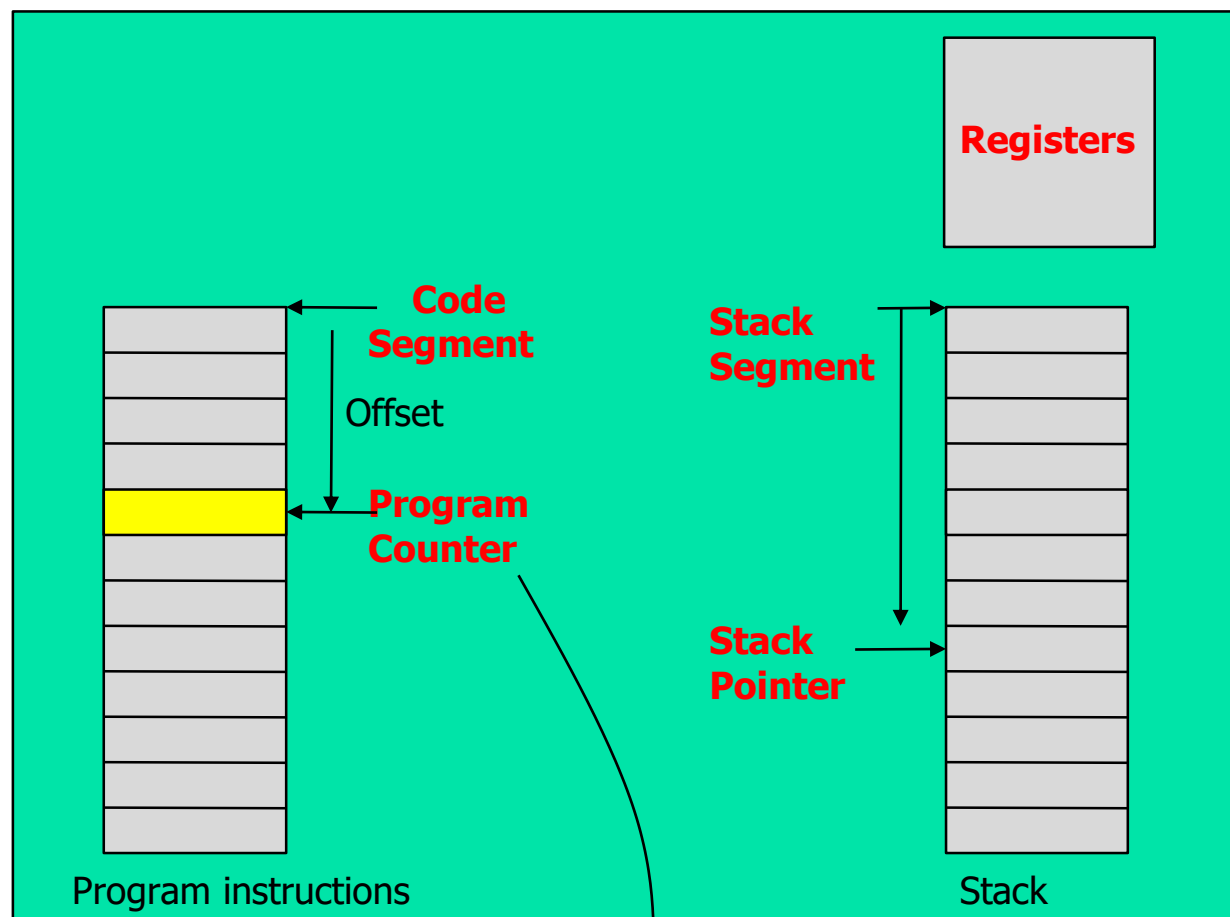

Save PC on thread stack
Jump to yield() function

CTX Switch: Yield

CTX Switch: Yield

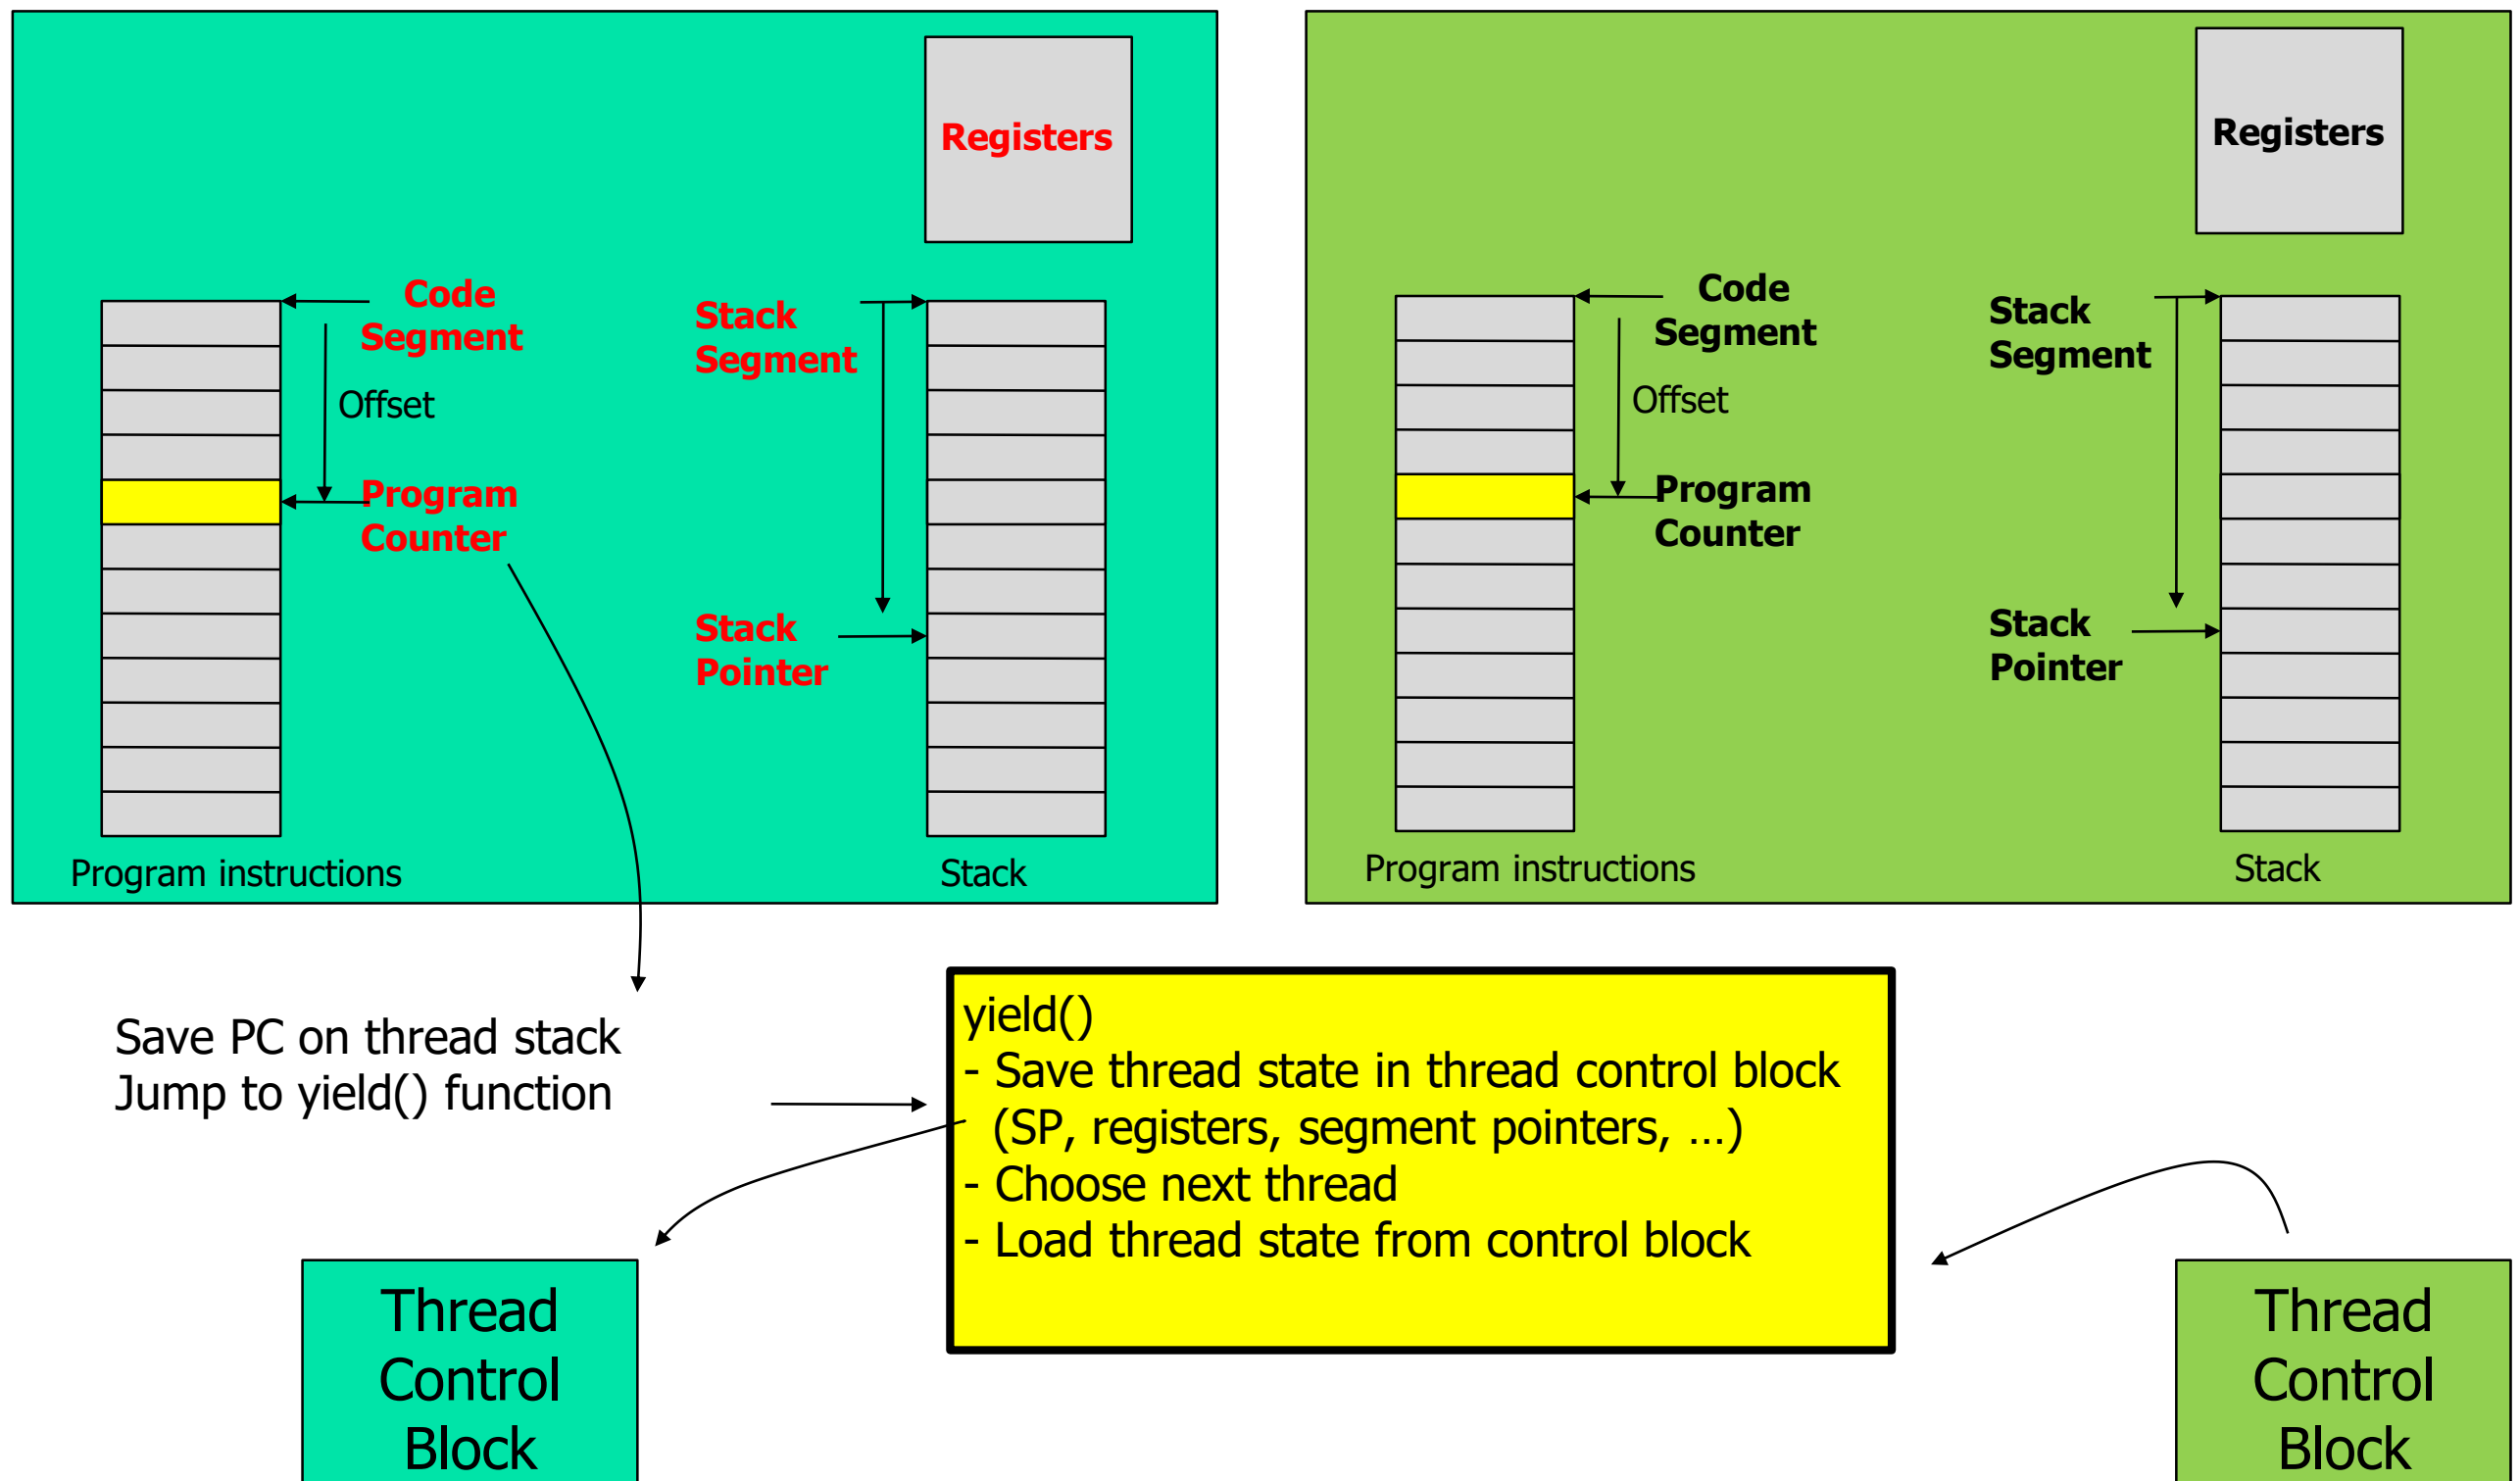

Save PC on thread stack
Jump to yield() function

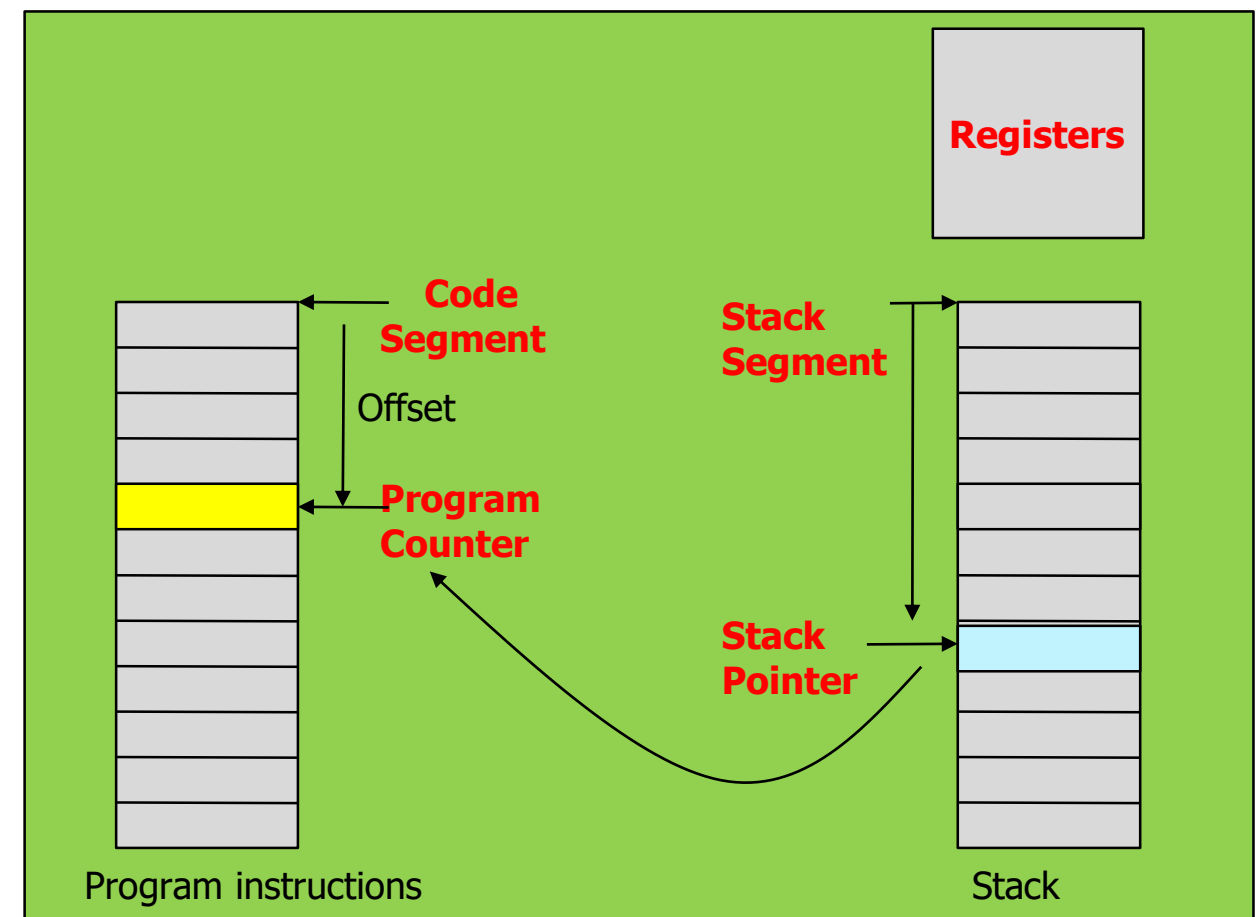

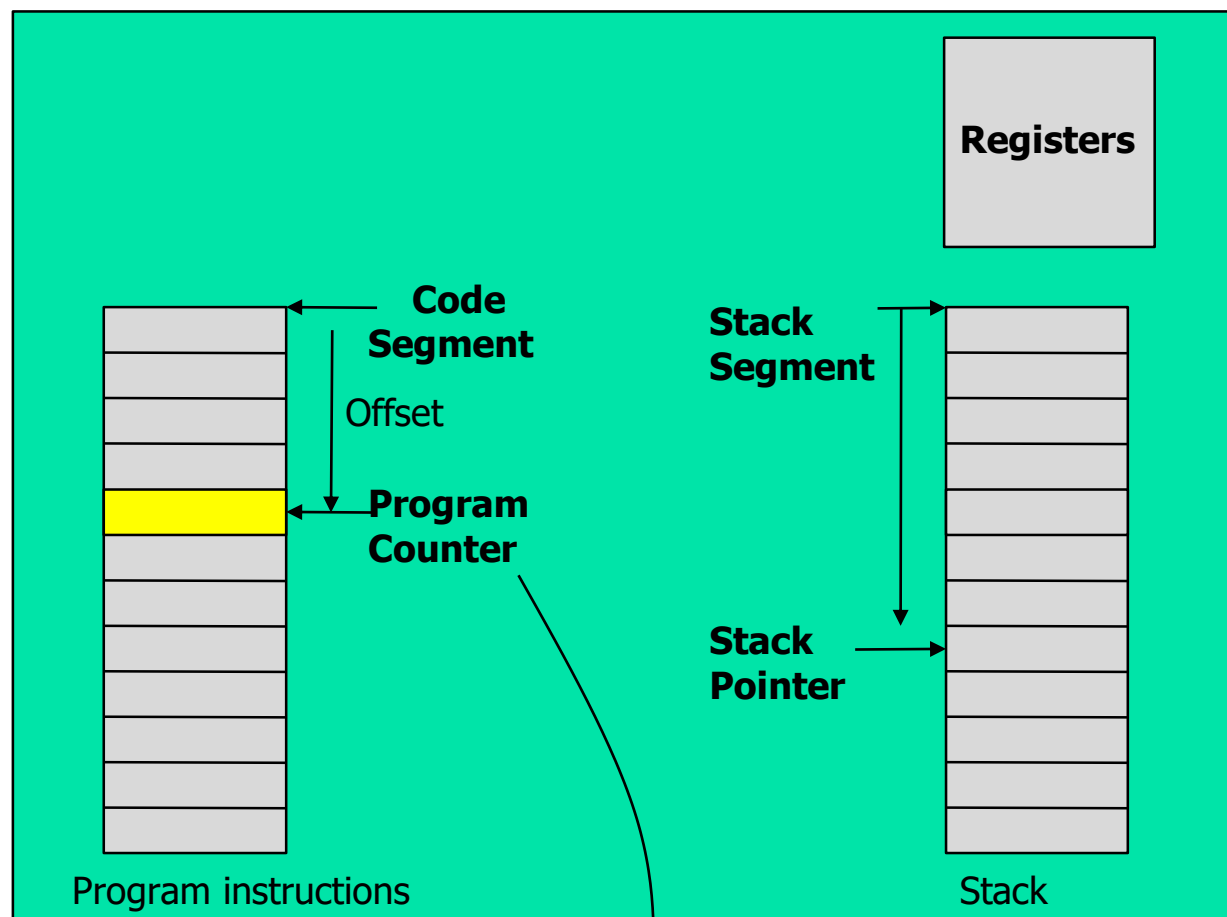

```
yield()  
- Save thread state in thread control block  
  (SP, registers, segment pointers, ...)  
- Choose next thread
```

Thread
Control
Block

CTX Switch: Yield

CTX Switch: Yield

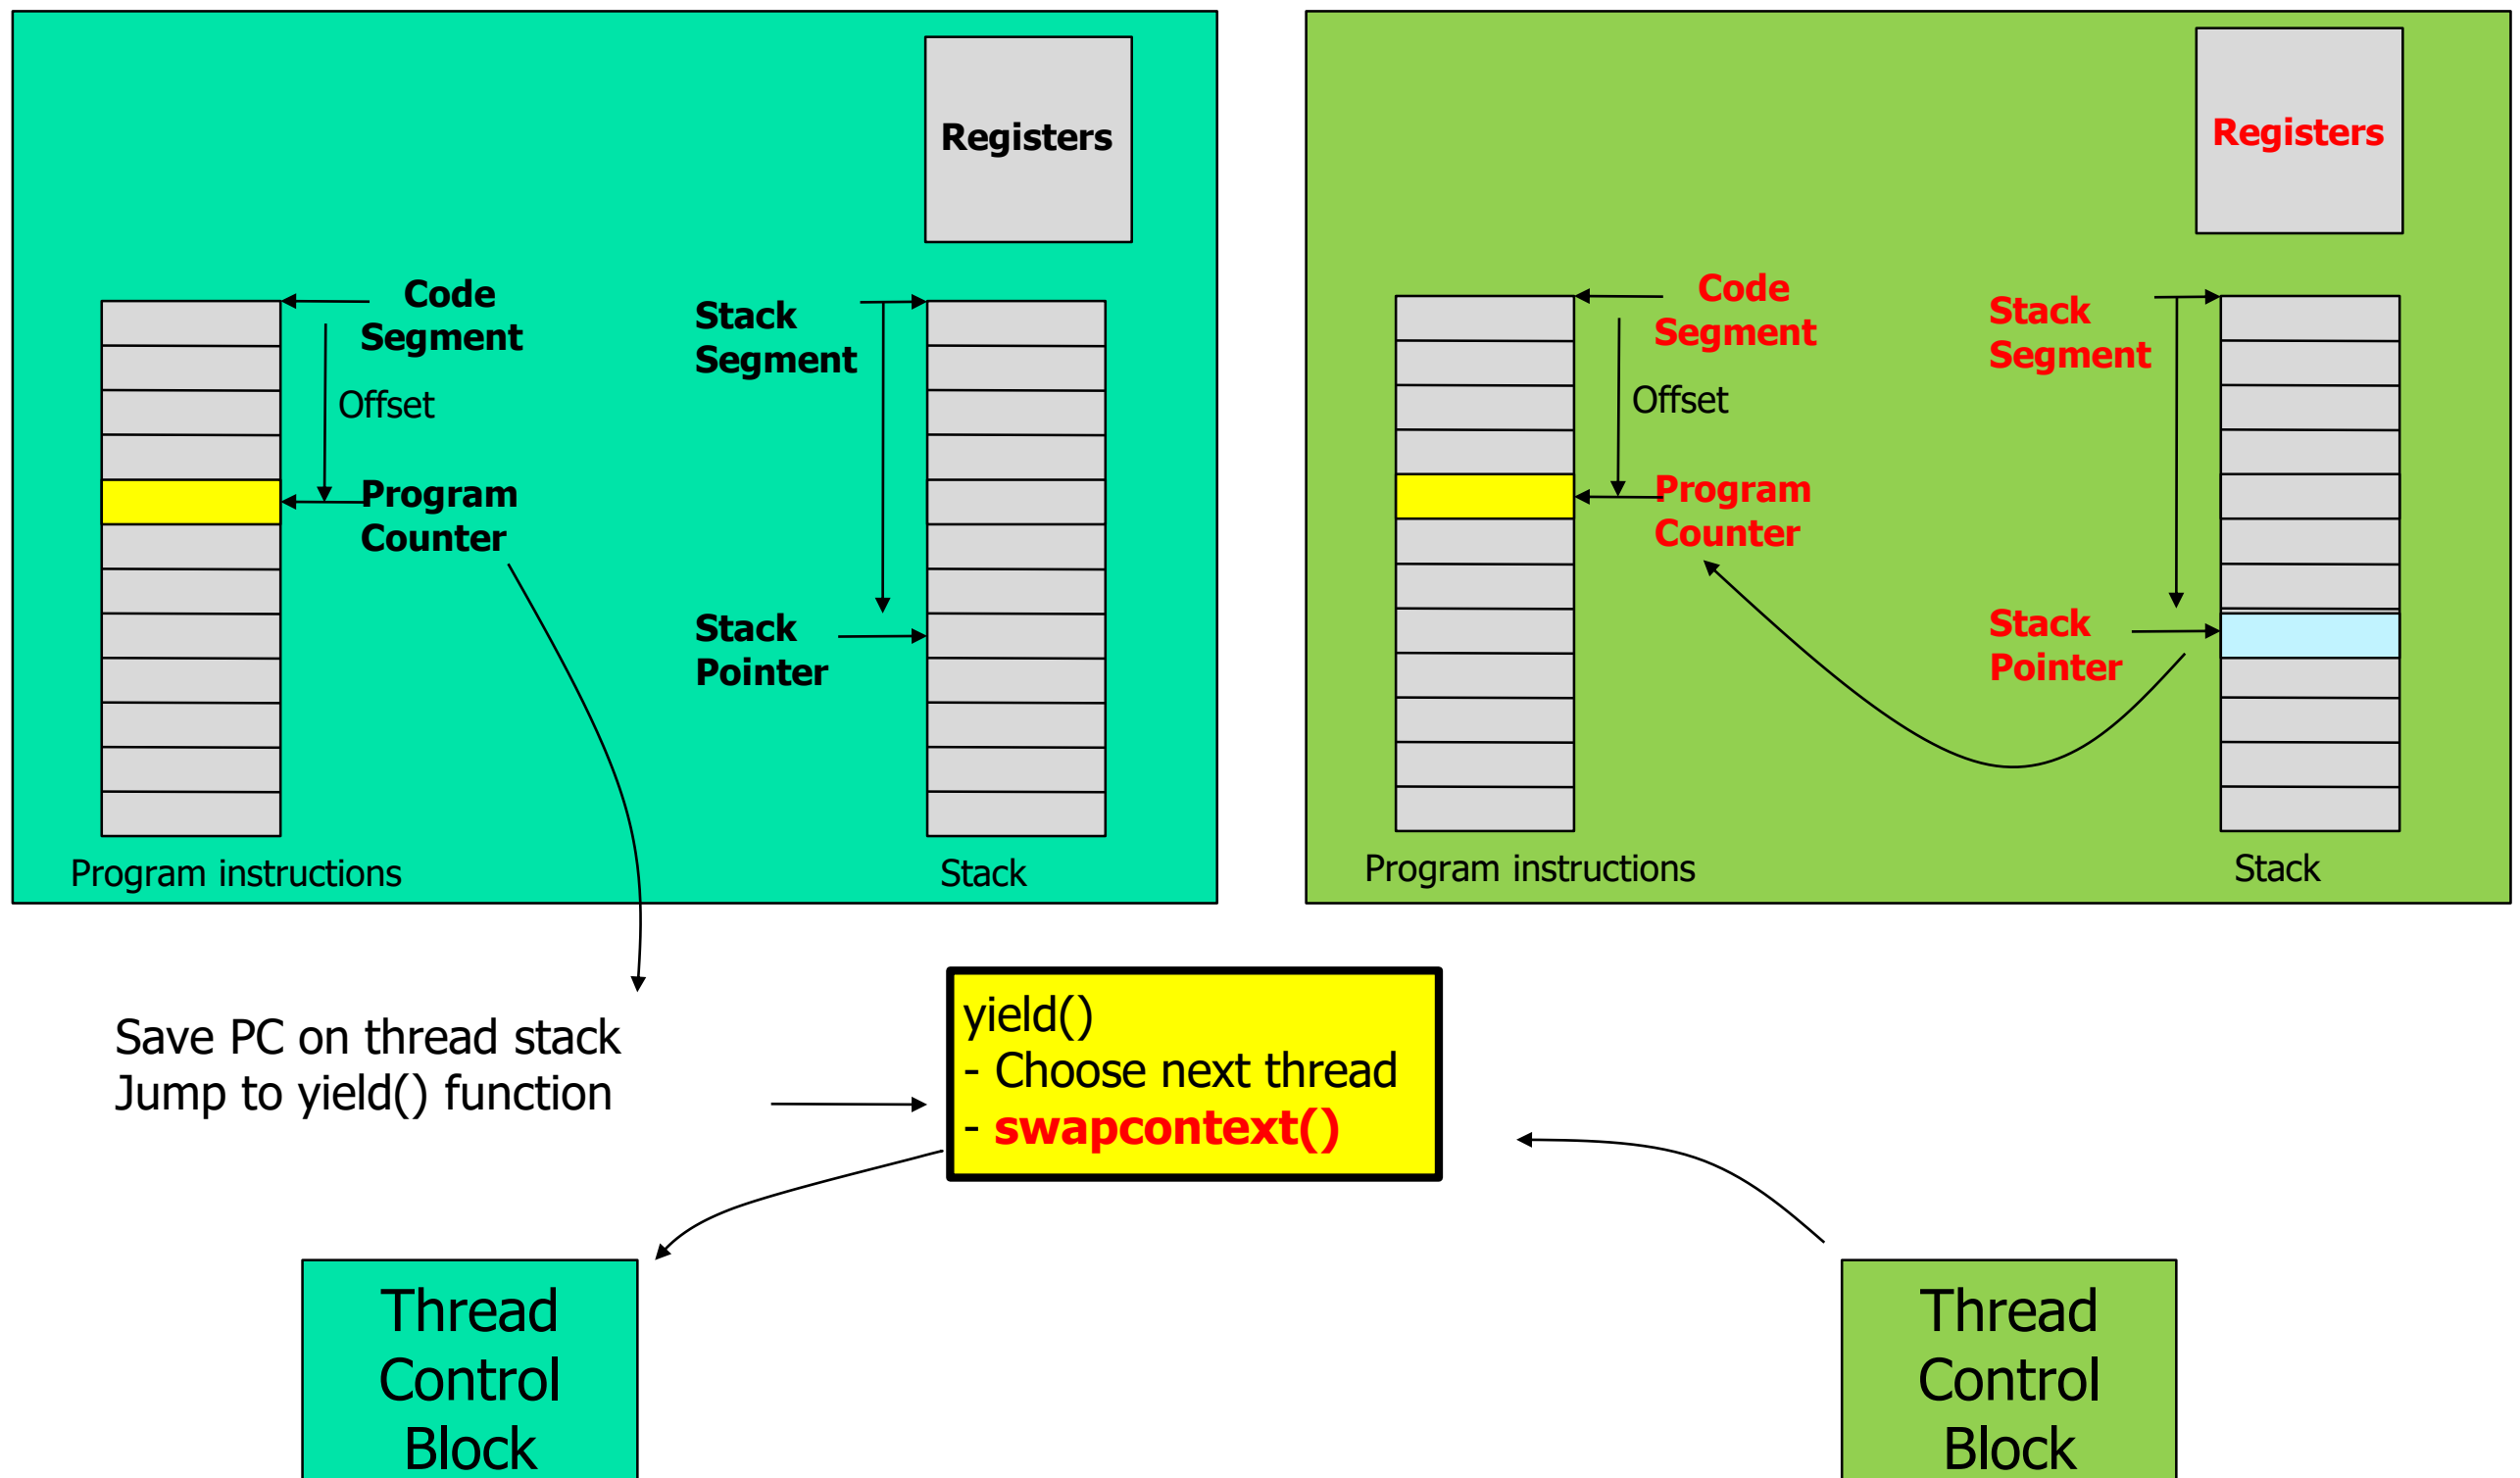

Save PC on thread stack
Jump to yield() function

Thread
Control
Block

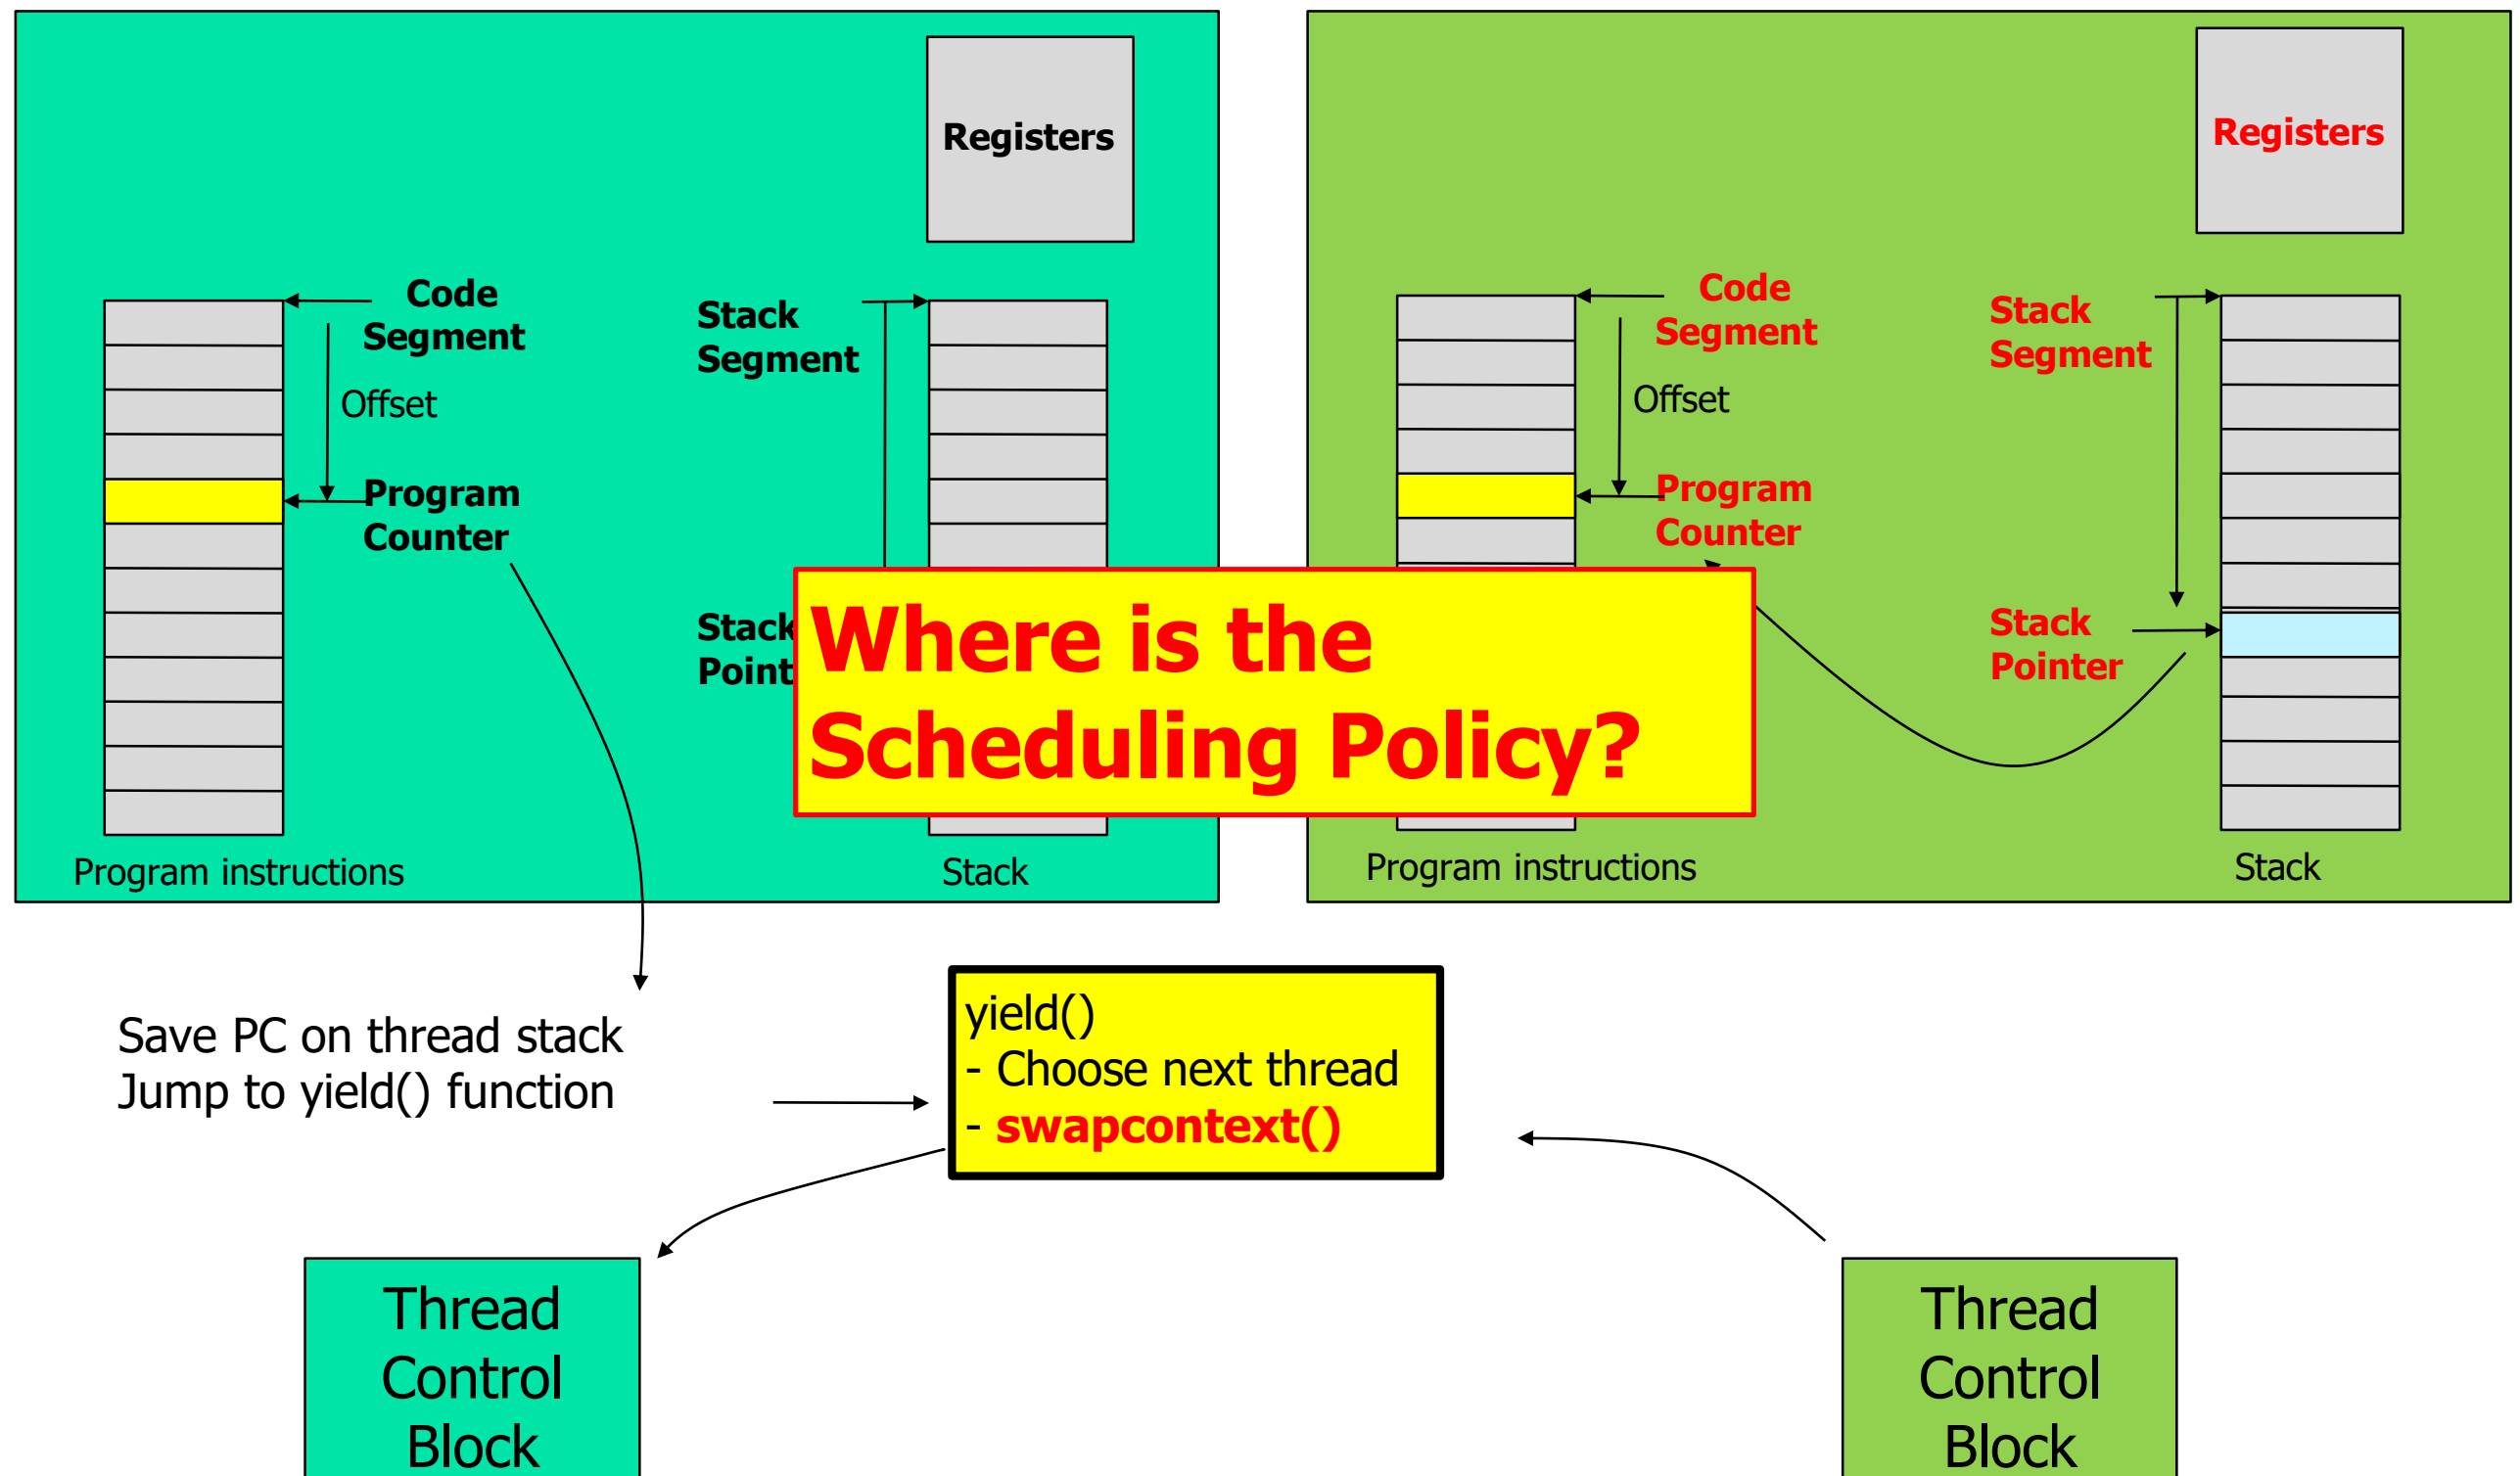

```
yield()
- Save thread state in thread control block
  (SP, registers, segment pointers, ...)
- Choose next thread
- Load thread state from control block
- Pop PC from thread stack (return from handler)
```
