# Storage Hierarchy

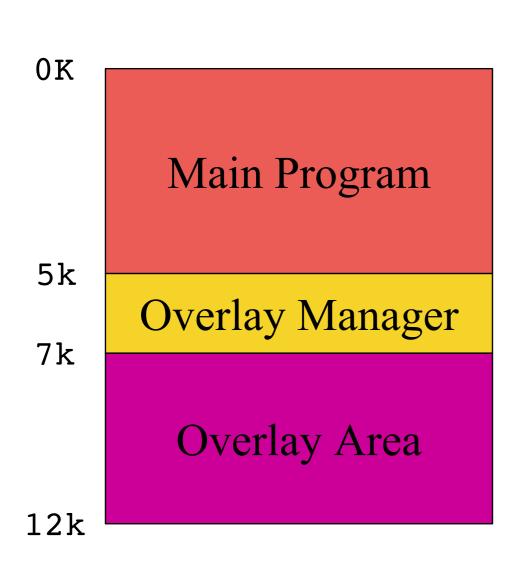

#### Problem Statement

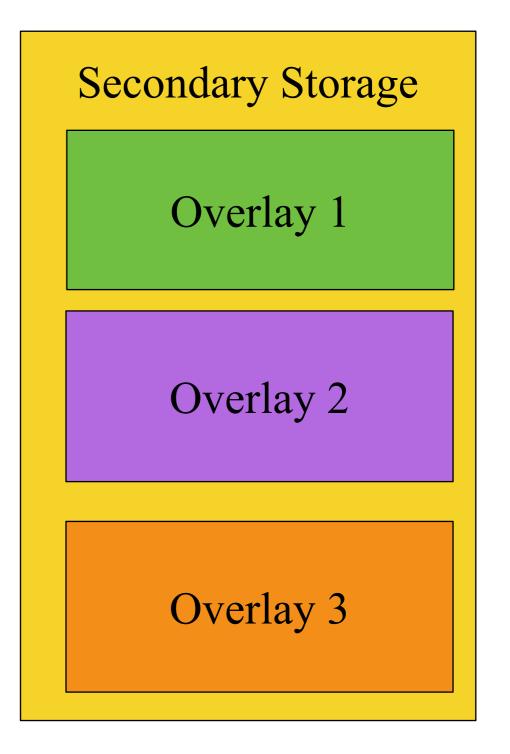

We have limited amounts of fast resources, and large amounts of slower resources...

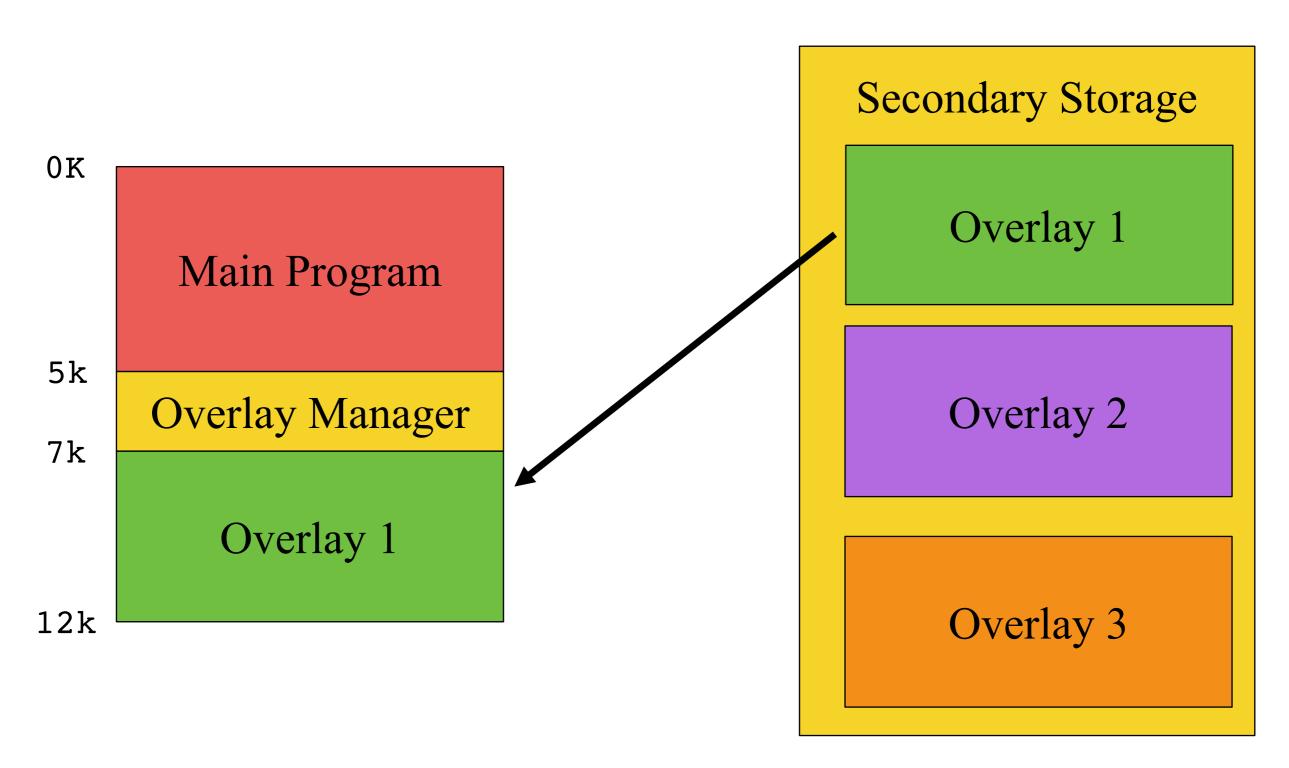

How to create the illusion of an abundant fast resource?

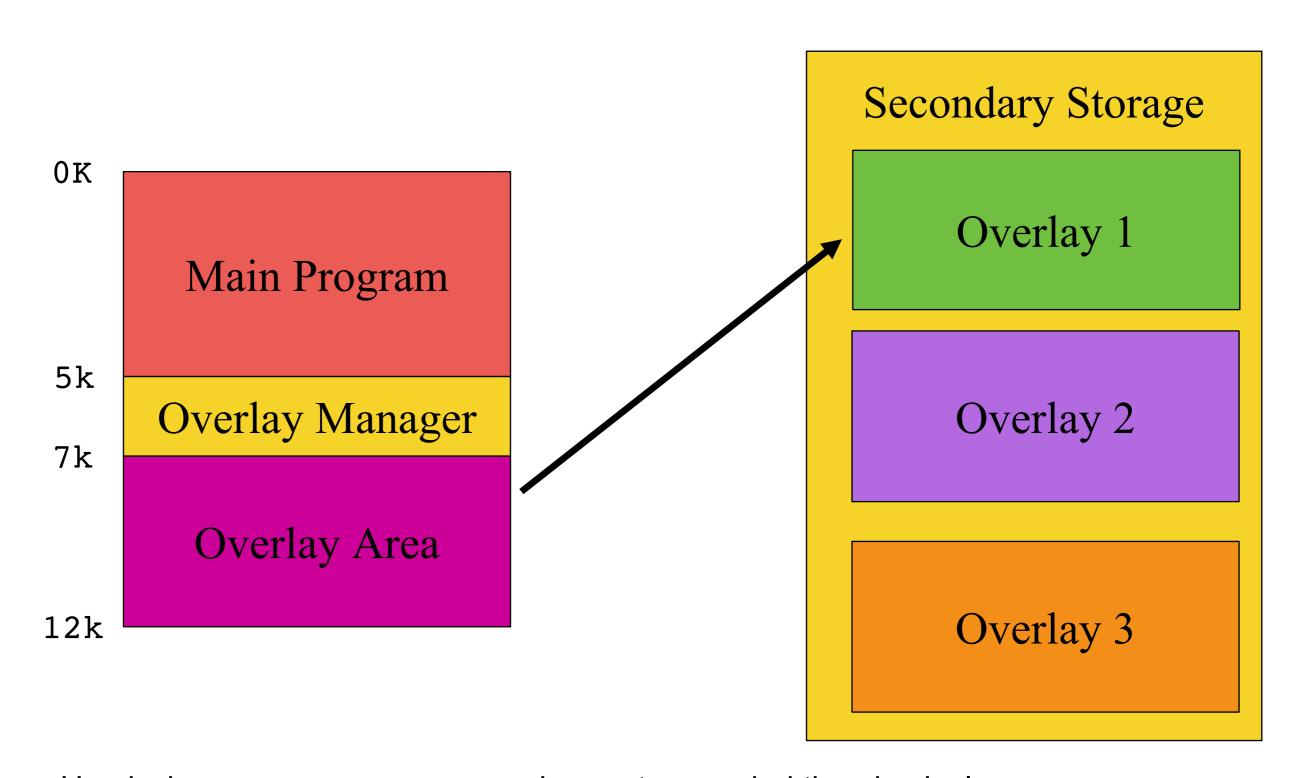

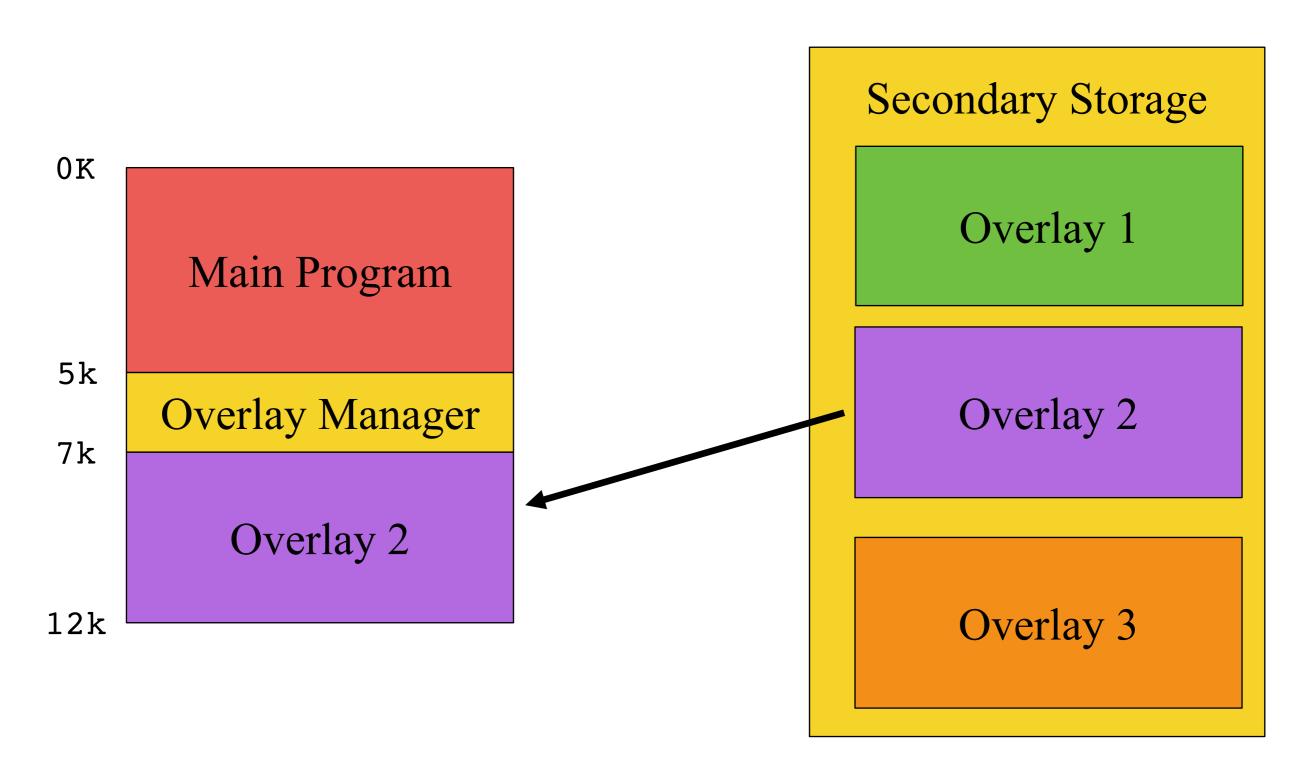

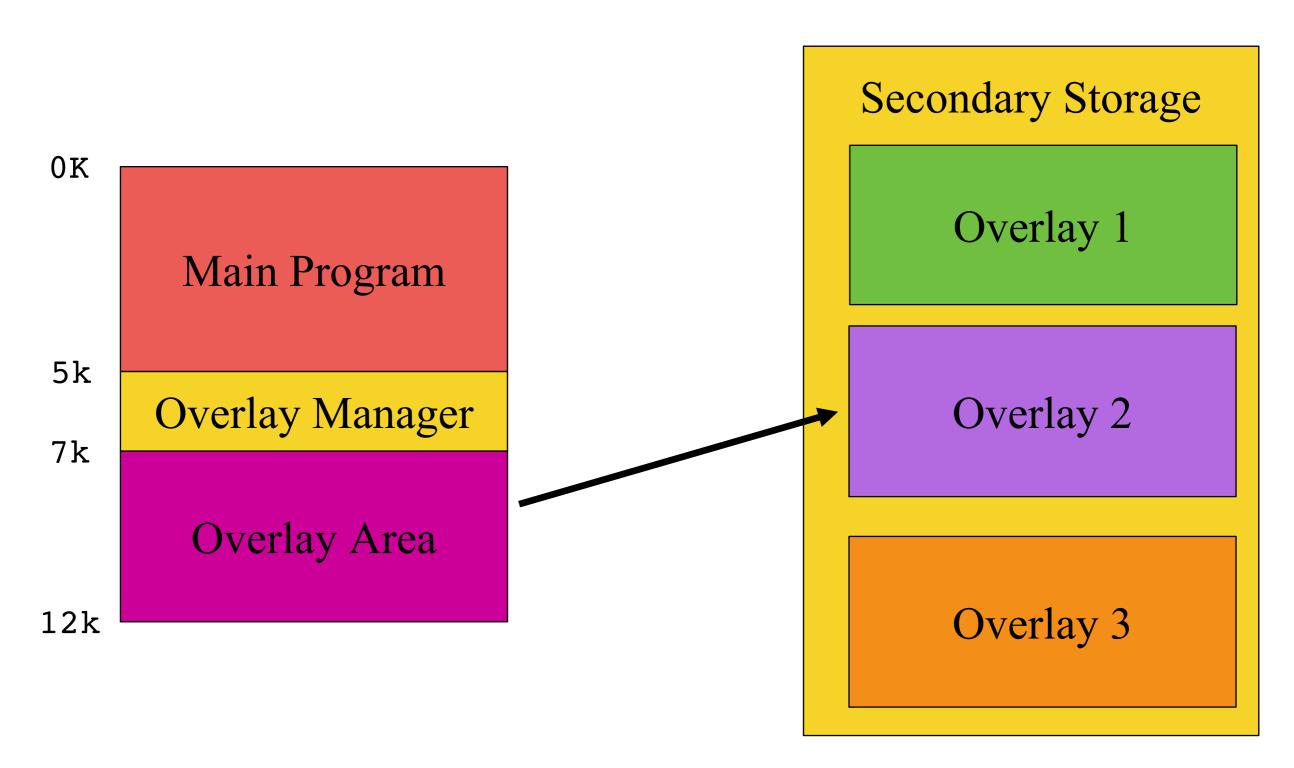

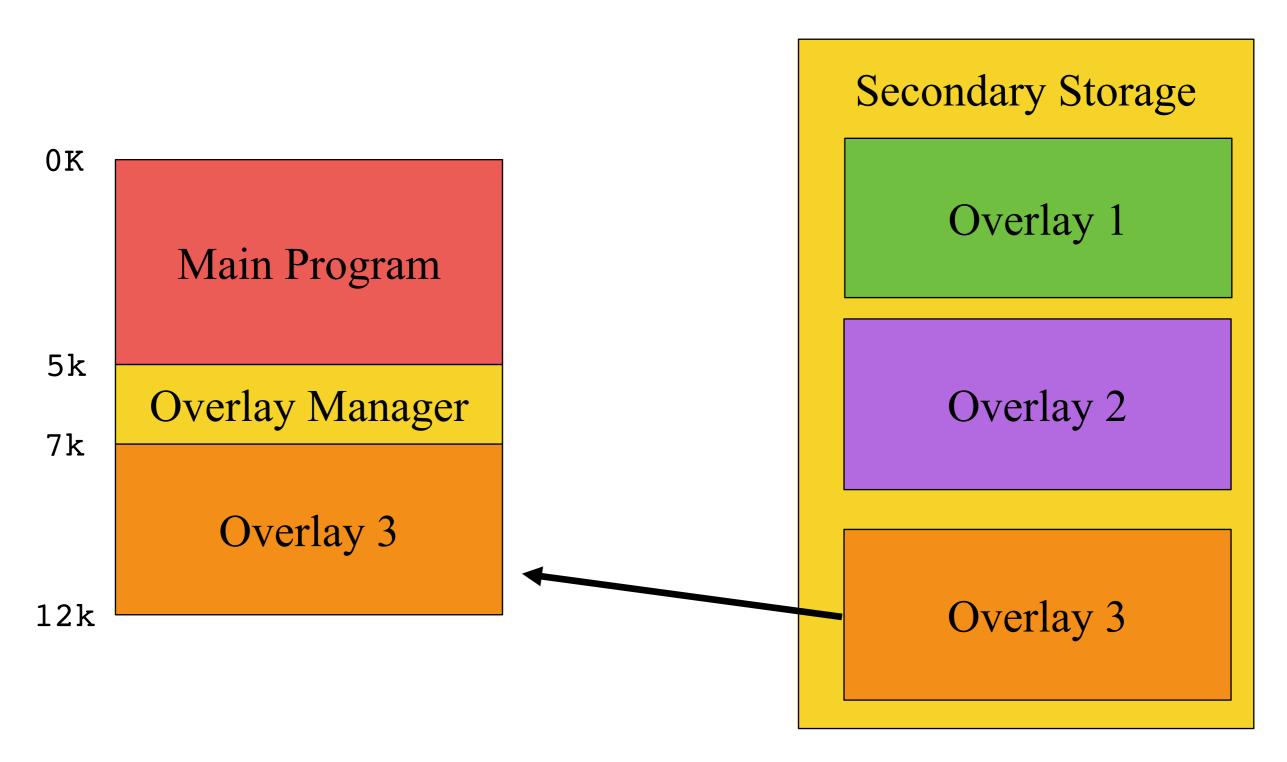

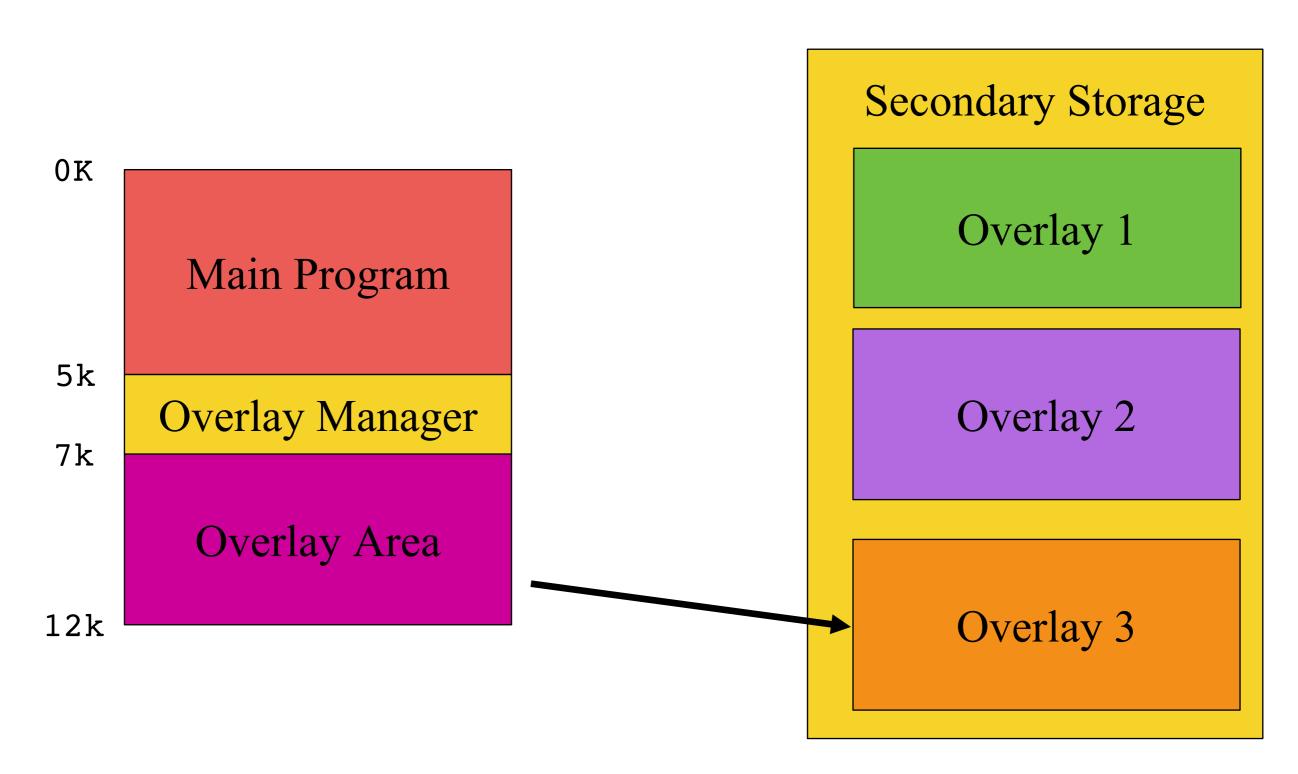

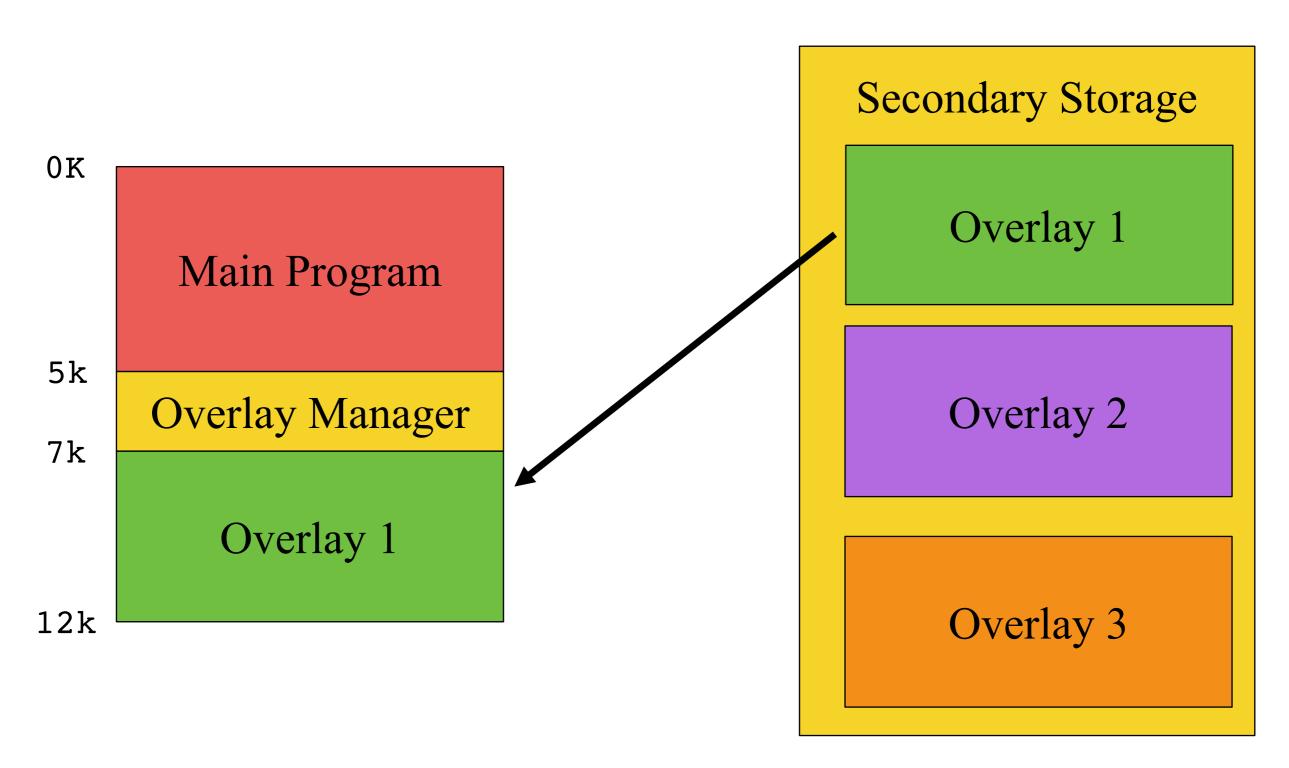

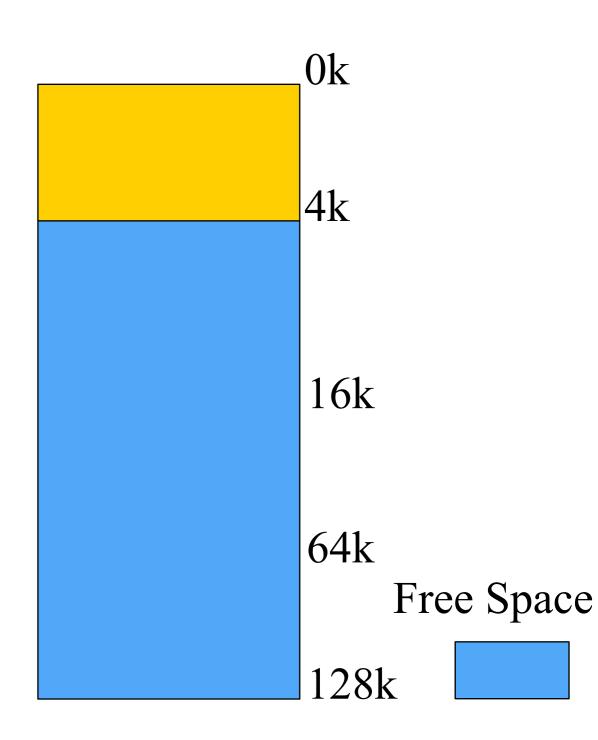

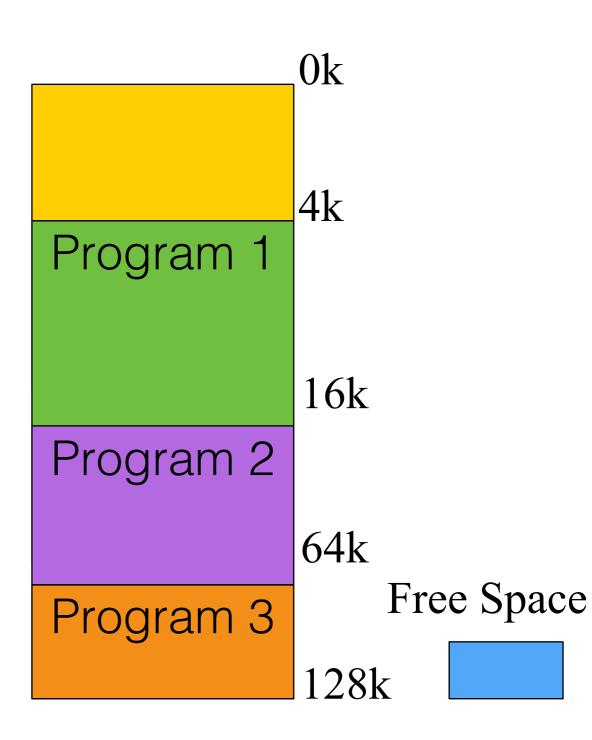

- Approach: Multiprogramming with fixed memory partitions
- Divides memory into *n* fixed partitions (possibly unequal)
- Problem?

- Problem?

- Approach: Multiprogramming with fixed memory partitions
- Divides memory into *n* fixed partitions (possible unequal)
- Problem?
  - Internal Fragmentation

- Separate input queue for each partition
  - Sorting incoming jobs into separate queues
  - Inefficient utilization of memory
    - when the queue for a large partition is empty but the queue for a small partition is full. Small jobs have to wait to get into memory even though plenty of memory is free.
- One single input queue for all partitions.
  - Allocate a partition where the job fits in.

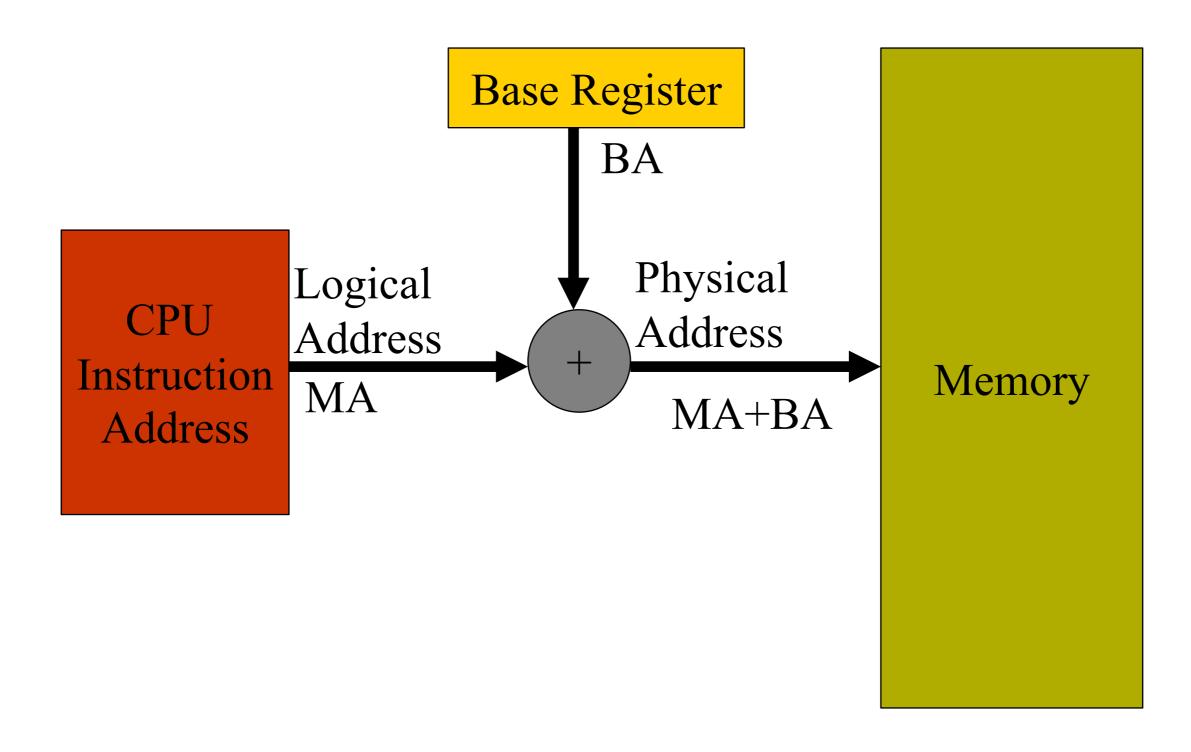

### History: Relocation

- Correct starting address when a program should start in the memory
- Different jobs will run at different addresses
  - When a program is linked, the linker must know at what address the program will begin in memory.
- Enter "Logical addresses"
  - Logical address space , range (0 to max)
  - Physical addresses, Physical address space range (R+0 to R+max) for base value R.
  - User program never sees the real physical addresses
- Relocation register
  - Mapping requires hardware with the base register

### History: Relocation Register

# History: Variable Partition Allocation

1 Monitor Job 1 Job 2 Job 3 Job 4 Free

Memory wasted by **External Fragmentation** 

### History: Storage Placement Strategy

**Best Fit?** 

Next Fit?

### Virtual Memory

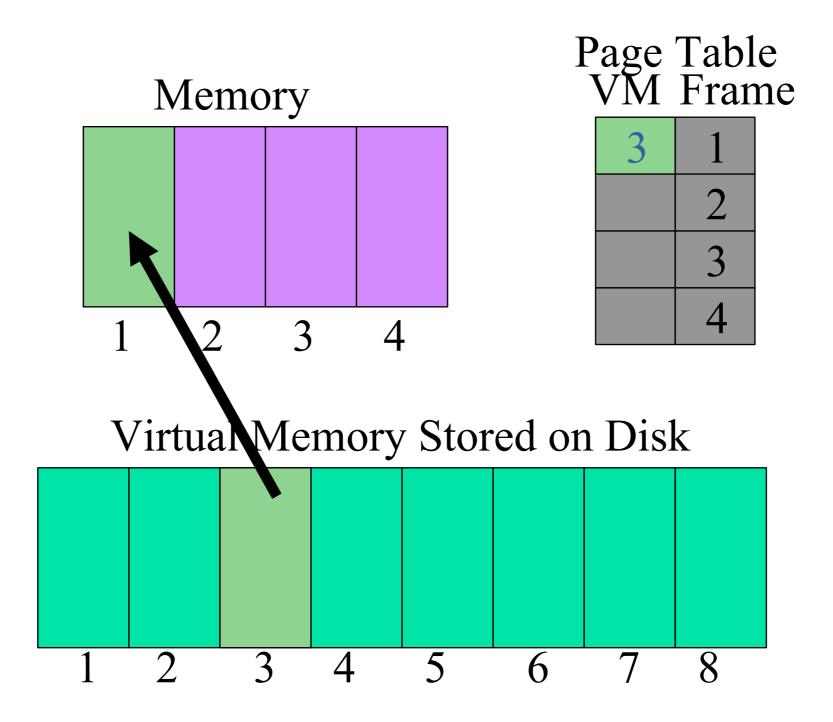

- Provide user with virtual memory that is as big as user needs
- Store virtual memory on disk
- Cache parts of virtual memory being used in real memory
- Load and store cached virtual memory without user program intervention

Request Page 8. Swap Page 1 to Disk First...

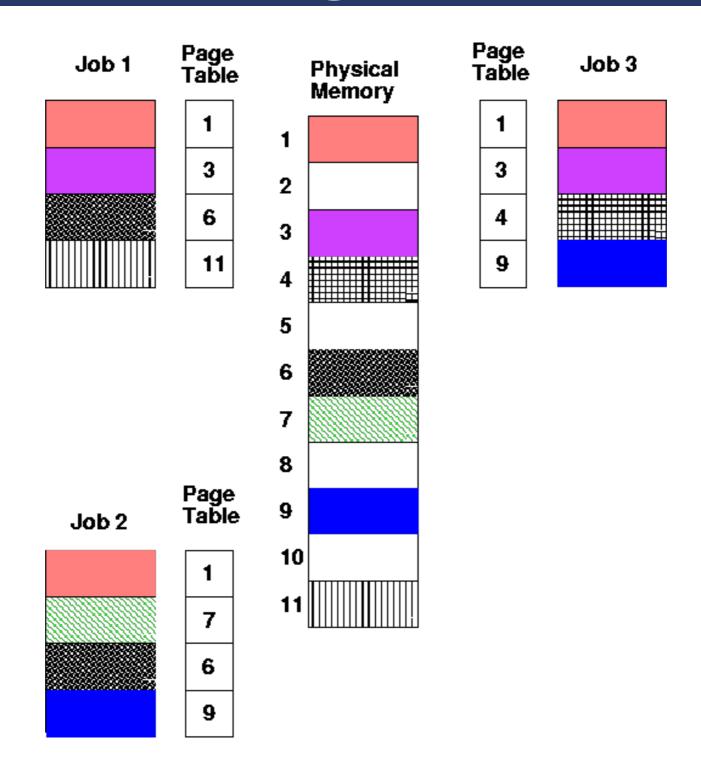

Request Page 8. ... now load Page 8 into Memory.

# Shared Pages

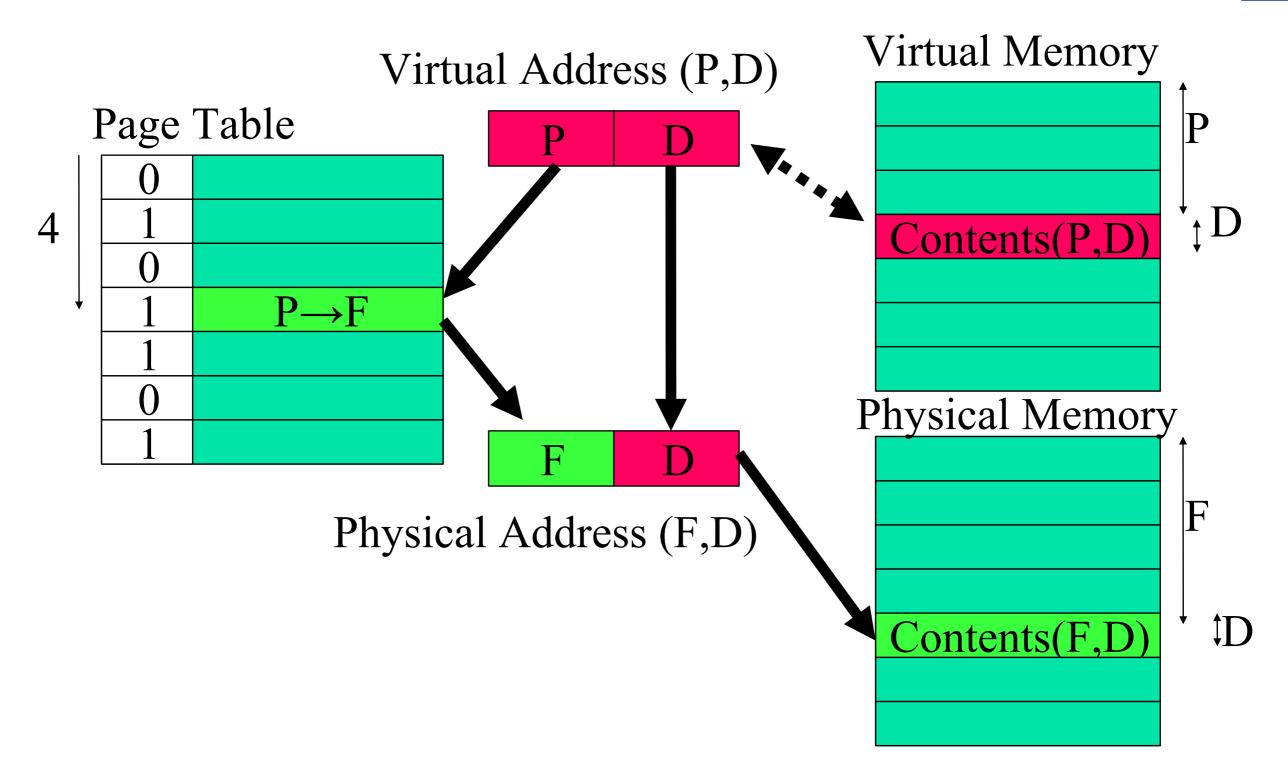

Note: Virtual Memory also supports shared pages.

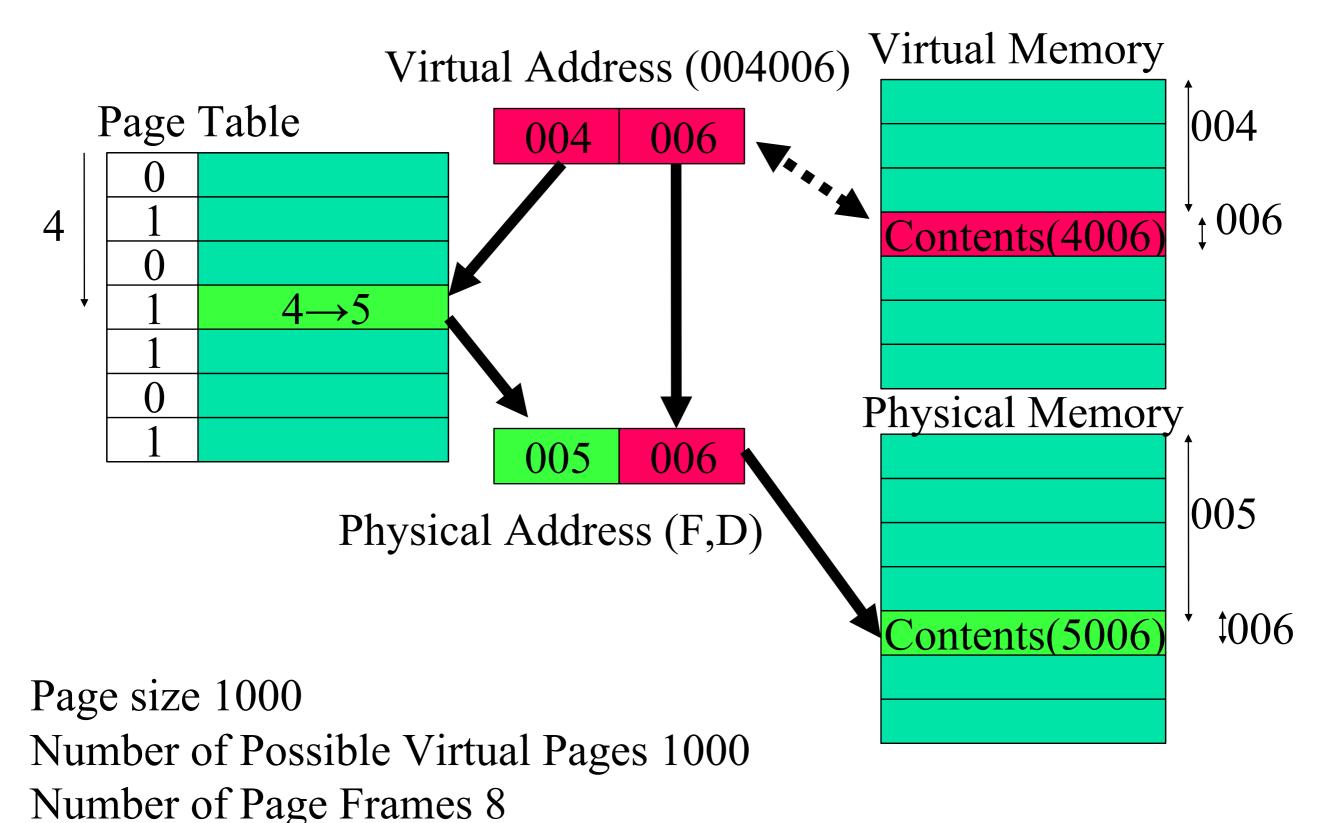

# Page Mapping Hardware

# Page Mapping Hardware

### Page Faults

- Occur when we access a virtual page that is not mapped into any physical page
  - A fault is triggered by hardware
- Page fault handler (in OS's VM subsystem)
  - Find if there is any free physical page available
    - If no, evict some resident page to disk (swapping space)
  - Allocate a free physical page
  - Load the faulted virtual page to the prepared physical page
  - Modify the page table

### Reasoning about Page Tables

- On a 32 bit system we have 2^32 B virtual address space
  - i.e., a 32 bit register can store 2^32 values
- # of pages are 2<sup>n</sup> (e.g., 512 B, 1 KB, 2 KB, 4 KB...)
- Given a page size, how many pages are needed?
  - e.g., If 4 KB pages (2^12 B), then 2^32/2^12=...
    - 2^20 pages required to represent the address space
- But! each page entry takes more than 1 Byte of space to represent.
  - suppose page size is 4 bytes (Why?)
  - (2\*2) \* 2^ 20 = 4 MB of space required to represent our page table in physical memory.
- What is the consequence of this?
